In selecting a steam equipment, we should usually get an engine a little more than equal to the demand for power at the moment. This makes it possible to add a new machine in the shop or to push the work there a little more heavily when some extra demand is made. Then get a boiler that is distinctly more than equal to the engine. For example, it is in effect recommended by competent authority to use, say, an 8-horse-power boiler for the case where one of 6-horse-power could be made to do the work. It will do the work better than the smaller one and with greater economy. In short, get an engine bigger than the work in sight and then get a boiler bigger yet.

Types of Steam Engines.

The simplest of all types of ordinary steam engines is the plain slide-valve machine. A representative stationary unit of this type will have a long bed of cast iron resting on the concrete or other foundation block. At one end are two bearing boxes in which is carried the engine shaft. This shaft is transversely arranged, and will have mounted on its two ends two fly-wheels, one on each end. The engine shaft is really a crank shaft. At the other end of the bed is arranged the cylinder. In it is a piston which moves back and forth horizontally. The piston has attached to it a piston rod which moves in a straight horizontal line. A piece called the cross-head is secured to the other end of the piston rod. The cross-head slides to and fro in suitable guides. As the steam forces the piston in the cylinder to shift back and forth, the result is an equal and similar movement of the piston rod and consequently of the cross-head in its guides. So far, we have nothing but a to and fro motion in a horizontal straight line. These movements should nevertheless be very perfect. It is this back and forth movement that gives to the ordinary apparatus the name of reciprocating engine.

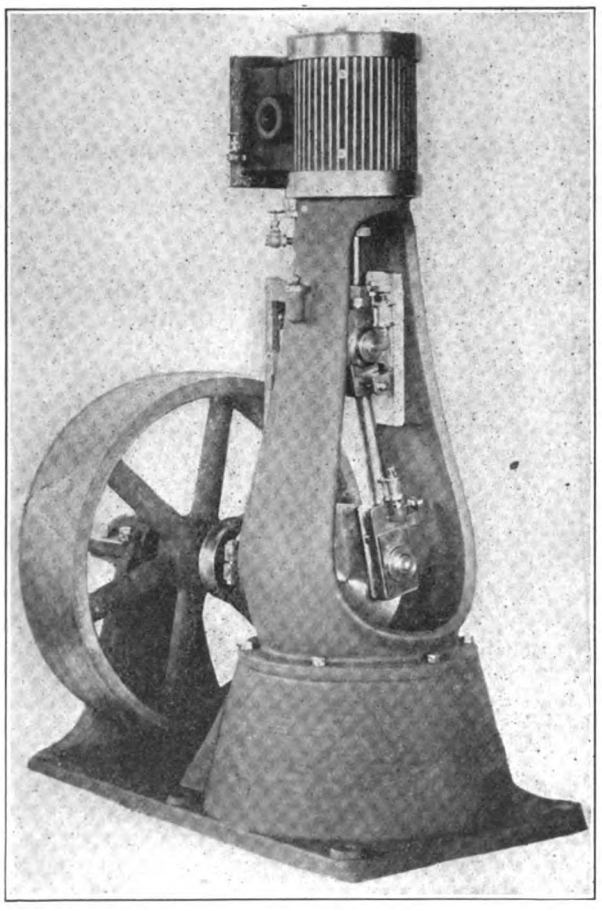
We must get rotary motion in order to drive a line shaft. This is accomplished by using a connecting rod. This rod is pivoted at one end to the cross-head by the cross-head pin or wrist pin, and at the other end to the crank shaft by the crank pin. The crank pin may be one solid piece of metal with the crank shaft.

The two fly wheels instead of one are for the purpose of even running. Counterweights are secured to the crank to balance the weight of the crank, crank pin and part of the weight of the connecting rod. They also promote even running.

The cross-head should fit snugly in its guides. It should move easily back and forth in them with no tendency to bend the piston rod. Arrangements providing correctly for these things promote evenness of running.

A solid foundation block and an engine set on it so as to have the piston and cross-head guides absolutely horizontal and the axis of the shaft also exactly horizontal will tend to even, correct running. The matter of correctly setting the engine on the block is so important that it may be well to be still more specific. It is not the bottom of the bed that we want horizontal. Pay no attention to it. When the bed is let down to within, say ¾ inch of the top to the concrete of the block, this occurring before the cement mortar is put on, we block it up with pieces of bar steel plate. Now we must do the blocking-up in such way as to get the engine exactly right. We lay a level across the two bearing boxes and make sure that we have the bottoms of these boxes in a line that is exactly horizontal. As we may have trouble in using the level with its flat bottom for this purpose, we may interpose a short length of accurate line shafting. We lay the shafting in the boxes and then place the level on top of the shafting. Instead, we may put the crank shaft in place and test this shaft with the level. We must also test the cross-head guides (or some other part) in order to see whether the bed is exactly level longitudinally. Do not rest, if there is the slightest thing wrong when leveling lengthwise and crosswise. The cement mortar that is put in place after we are through blocking-up is to secure the engine in the position we leave it when we finish blocking.

The size of an engine is not expressed by its weight or the room it takes up, but by the diameter of the cylinder and the length of movement of the piston or cross-head. For example, an engine having an 8-inch cylinder and an 11-inch stroke is called an 8"x11" engine.



It is recommended that one should not economize

Digitized by Google

on the accessory appliances for a steam plant. That is, we "should have a good pump, a good ejector, a good heater, an extra steam gauge, an extra fusible plug ready to put in, a flue expander and a beader." There should be a good outfit for cleaning the boiler. As to lubrication, it will be best to use the lubricants that have been found the most suitable. Do this regardless of the price of the lubricant—of course, within reason—resting assured that it is good economy to protect expensive parts by good lubricants. Besides, lubrication difficulties may result in a shut down, which may turn out to be quite an expense.

Setting the Boiler.

It is very important to have the boiler set right. Here it is not a question of the exactly horizontal

Usual Type of Vertical Steam Engine.

and the exactly vertical, but a question of providing proper arrangements for the burning of the coal. Ordinarily, it will be best to have a big space. The reason is largely as follows. It is important, not to say necessary, that the combustion of the coal be complete before the boiler surface is reached by the flames. It takes time and space for the gases which come from bituminous coal to go through the burning operation. They have to get mixed with the air and have to reach a considerable temperature. These two thing are accomplished largely as the gases move towards the boiler. If the distance is too short, there will be too little time or too little space for the purpose. After any unburnt gases have once struck against the boiler, we cannot expect them to unite—the boiler chills them too much. It is wise, then, not to have the bed of coals too close up to the boiler. Too short a space between coal and boiler seems to have been, and still seems to be, a pretty common error.

Sometimes in running the fire for the boiler, a good deal of trouble arises because of clinkers. If clinker troubles occur in the power plant of the repair shop, it may be well to experiment a little. First, try mixing the coal with a little sand. Do the mixing before the coal is put on the fire. If this improves matters, increase the amount of sand and you may perhaps cure the trouble altogether. If the sand does not help, then try oyster shells or lime. If shells are used, break them up first. In either case, do the mixing before putting coal into the boiler furnace. One kind of coal will require sand; another will require lime or a substitute. The easiest thing to do is to try one and if need be the other.

(To be continued.)

AMONG INDIANA GARAGES.

Too Much "Free Air" and the Pernicious Racing Engine Practice.

BY JAMES F. HOBART, M. E.

"Free Air" is not always what it is cracked up to be and a number of garage owners are finding fault with the manner in which the air and its appliances, hose, etc., are treated by patrons who avail themselves of it. One man said he had to provide new hose about every two months. Another brought in that some of his free customers were never particular about turning off the air after they had used all they wanted, left the valve open a bit and he was at considerable expense to pump up air for filling the sky instead of tires.

Recently I came across a man who had evidently worked the free air business down to a pretty fine point. He said that air was a pretty hard thing to hold in pipes as air would find its way through a minute opening which steam or water would not even notice. He testified that he had been to considerable expense for compressed air to supply pipe leaks, losses of air from cracks in the hose where careless patrons had kinked the rubber tubing and broken it.

This man finally threw away the air pipe line and put in the device shown by Fig. 1. By the use of this device, patrons who wanted free air had to work a little bit for it and were not so careless about leaving hose underfoot or on the ground for wheels of automobiles to run over.

The apparatus was quite simple, consisting of a low truck A, mounted upon four heavy casters, B, B, B, and upon the truck was mounted a welded tank C which was fitted with an inlet pipe and valve D, to which was attached a union E, the other half of which may be found attached at Q, to the outlet pipe of an air pump shown by Fig. 2. The tank is fastened to the truck by means of two strap rods F, F, and is tightened fast thereto by means of eye bolts which screw fast underneath the truck. At G a pressure gauge is located and a safety valve is placed at H, both these being connected with the same pipe, and by means of a T, with the tank at I.

To protect the pressure gauge and the safety valve, a broad metal band is arched over the tank, as shown at J. This piece of metal is about ¼ inch thick and about 4 inches wide. This band is fastened to the truck at K. A handle is attached at L, by

Digitized by Google

means of which the truck may be moved around at will, the casters will permit the truck to turn at will in any direction and it may be turned around in its own length.

At M is inserted a nipple and valve by means of which the air may be drawn off at will as required for filling a tire. A short length of hose, N, is fitted at O, with the usual connection for tire-filling and when a customer desires a little air, he comes into the shop, trundles the cylinder out to his car, fills as many tires as he wishes, and goes away rejoicing, provided he has not presumed upon the generosity of the garage man and tried to get something for nothing by taking more air than his tires really need.

The garage man has protected himself against this kind of hoggishness in a very effectual manner by keeping the tank charged to about 250 pounds per square inch. Then, if the customer chooses to take more air than is necessary simply because he is getting it for nothing, he will quite likely hear his tire, particularly if it be an old one, go out with a "pop," which tells everybody around just what has happened.

By exercising a little care, a tire may be filled just right from a tank which has been charged with 250 pounds pressure, or even with 500 or 1,000 pounds to the square inch. If the filler will feel of the tires half as often as he does when pumping up by hand, he need never burst a tire when filling from a tank charged with air under a pressure of 250 pounds per square inch. But, when a man has enough air in a tire, and lets in more, just because the air is free, he is very apt to get his "come-uppance" when doing it with the 250 pound pressure.

The garage man told the writer of one chap who came along and proceeded to hog air to the extent of blowing up a tire with a resounding "bang" which knocked a whole lot of dust off the floor beams overhead. And, not satisfied with that, the

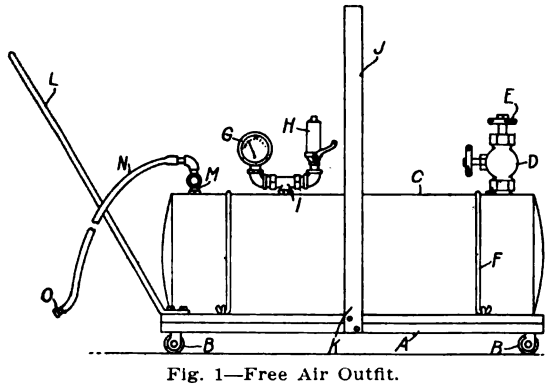


Fig. 1—Free Air Outfit.

same man at once proceeded to fill another tire, hogged the air again in spite of the lesson he had just received, and "bang" went the second tire! The man began to "tumble" to the racket, right then and there, and got so mad that he would not let the garage man fix up his tires, but went off upon two flat wheels to a neighboring garage and there had the two tires fixed up.

"It's all right," said the garage man. "If he hogs my air and bursts a tire, I will get my commission on it all right, whether I repair the break or he gets it done down the road, for you see, it's this way: The chap next to me, on either side, has put in an air tank just like mine and if an air hog takes too much air, blows up a tire and gets so sore that he wont have it repaired there, but comes to me or to the third man down in the other direction, why then I get the benefit. The chap where this man is doubtless going will gain the profit of repairing the two tires that air hog just blew up in this shop, and so it goes, we get the fellows who suffer in the other shops and it comes out about even in the end.

"I find," continued the garage man, "that it costs far less to maintain this tank arrangement than it does to operate a fixed tank with a pipe line and hose to the sidewalk. To be sure, there are some car

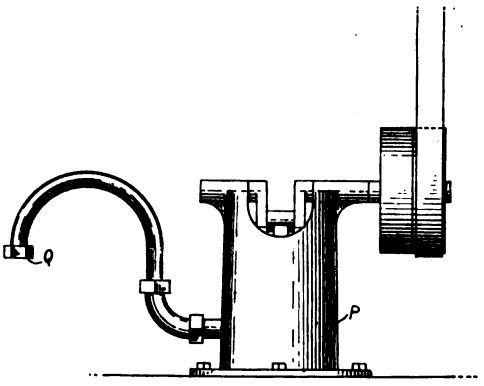

Fig. 2—Belt Driven Air Pump.

drivers who are too lazy to come in and push the truck out to the car,, but I can get along without the custom of such people and do not miss their trade.

"Most of my regular patrons appreciate my position and are glad to push the truck alongside. They also are decent about using the air. They realize that they can get air at any time and are careful about filling their tires and never have a blow-out from too much pressure. No, it's only the free air hogs who suffer from the heavy tank pressure, and as I regard all such customers as lawful game for their own cupidity, I have never the least qualm of conscience about letting them blow their tires sky-high if they choose to do so. There is the pressure gauge on the tank. They can see what air pressure is inside, and govern themselves accordingly, or let their tires 'go bang!' just as they choose."

The tank shown by Fig. 1 has welded seams. There are no rivets or solder to leak. The side seam was evidently welded by the oxy-acetylene process and the heads were put in by the same process. The head, which is visible in Fig. 1, is curved outward to a radius equal to the diameter of the tank. The other head, the one which is not visible, is made to the same curvature, but is placed the other side out, the curvature extending into the tank. The flange of this head is pressed into the tank about a half inch beyond the end of the tank and there welded fast. Evidently there is no leakage from this tank save what there may be around the three pipes which have been screwed into the shell, through reinforcing pads, which in turn have been securely welded to the shell of the tank. Should the three pipes also be welded in place, there could be no leakage save through the valves to which the pipes were attached. The garage man advised the writer that upon the only occasion he had ever tried the experiment—once when he was absent for two months—the pressure gauge had shown a loss of only five pounds pressure during that time, the tank being

Digitized by Google

left fully charged to 250 pounds and the gauge registering 245 pounds upon his return after eight weeks' absence in hospital. Therefore, it is evident that a welded air tank, well piped, is pretty safe against air-loss by leakage.

Charging the Air-Cylinder.

The air pump, by means of which the cylinder was charged, was a small, single vertical belt driven affair which, as shown by Fig. 2, was securely fastened to the floor of the garage, as indicated at P. The air outlet, as shown, was piped so as to give a vertical outlet to which was attached a "goose-neck" which terminated with half a screwed union, Q, the other half of the union being located at E, Fig. 1, on top of the air tank.

When the air in the tank needed replenishing, the truck was trundled to the air pump and the portions of the union brought vertically even with each other. There was enough elasticity in the goose-neck to permit the union being screwed together, valve D was opened, and the tank was ready for charging.

The power equipment in this garage or repair shop was quite simple and evidently fully ample for shop needs. A shaft about 12 feet long was hung to the overhead floor timbers. A gasoline engine placed in a corner was belted to the shaft, and arranged along its length were pulleys for belts to the air pump on the floor beneath, also to drive an emery grinder, and a good drilling machine. The shop did not possess a lathe, but it did have a most excellent arbor or mandrel press, a massive affair, operated by a hand lever, and capable of pressing on and off any gear or other friction held device used in an automobile. The owner of the garage told the writer that he intended putting in a lathe, a shaper and a milling machine as soon as possible to do so, but that when he started the shop, he could afford only one tool besides the grinding wheel, so he chose the mandrel press and had never been sorry that he did so. It certainly is a great comfort to be able to slide gears on and off without the least danger of breaking or battering either gear or its shaft by hammer blows. He testified that he would not care to do automobile repair work without a good mandrel press—and the writer is sure that he is quite right therein.

Racing the Engine.

Probably not until "the fools are all dead" will some automobile drivers learn that to race the engine unnecessarily is wasteful both of gasoline and of engine life. Running an engine at full speed, idle, with the transmission disconnected at the clutch, has a very different effect upon the engine mechanism than when running at full speed pulling a load. The idle running is far harder upon the bearings, the pistons and the connections.

Still, many drivers seem to think it either necessary, or "smart" to often let the engine run at full speed for a minute or two before shutting down, or when starting up. Sometimes I hear engines racing when seemingly there can be no possible reason for it. Some drivers seem to have the idea that an engine will start better if, upon stopping, the engine be run at full speed for a minute or so and then stopped by cutting off the spark. This is a fallacy, which can only result in excessive wear of and strain upon engine parts. It was probably originated, this idea was, during the early days of automobile engines, when they were not as perfect as at present and did not always draw in gasoline charges at slow speeds, hence the fashion of racing the engine for a few revolutions just before cutting off the spark.

Probably, reasoning like Pat when ordered to take a teaspoonful of medicine each hour, and reasoning that "if a little will do me good, a lot will do me more good," he proceeded to take all the medicine in heroic doses in three hours, consequently requiring the assistance of the medicine man and a stomach pump in order to continue existence upon the earth plane. It is well, just before cutting off the spark, to stop the engine, to run it at regular touring speed for a revolution or two, just to be sure that there is a good supply of gasoline coming along. But, as for running the engine fast or racing it, just before stopping, is destructive and only causes an engine to go bad long before its time.

Bad Starting Up.

The habit of spinning or racing the engine just after starting up is also bad and equally destructive to engine parts when compared with the racing just before shutting down. If anything, the racing at starting is a little the worse of the two, for then the engine parts are often cold and the strain is worse than when the engine is hot.

I recently heard a garage man rebuke an engine driver for racing the engine when starting up. "I don't want the young men to get into such a beastly habit," he told the engine racer. "For it is foolish, useless and destructive and I intend to do all I can to prevent young drivers from acquiring it."

The driver who was thus rebuked took the matter in good part. "Why," said he, "I never realized that it did any harm, and always supposed it was the correct thing to speed up an engine just before shutting down, and again when starting up. But if it harms my engine, you can just bet that I'm going to cut it right out." And the garage man told me that in similar manner he had cured engine racing in a number of drivers.

One cause of engine racing at starting is that drivers will open the throttle for starting much further than is necessary and the engine begins to race almost immediately and continues to race until the driver can get to the wheel and cut off the excess of speed. This racing is just as bad as any, and there is no need of opening the throttle to a further extent than will give the engine a good easy speed after it starts. Lots of drivers start thus and their engines never race. One garage man showed me a throttle control which he had attached, which came through the bottom of the radiator and he could shut off as soon as the engine started without waiting to get to the wheel.

Injunction and Damages.

McQuay-Norris Mfg. Company of St. Louis, Mo., makers of Leak-Proof piston rings, were granted an injunction against Albertson & Company of Sioux City, Iowa, with damages, by Judge Reed of the United States District Court at Sioux City on May 29. Judge Reed sustained the copyright of McQuay-Norris Mfg. Company covering their book, "Dimensions of Piston Rings," and held that a book of piston ring sizes published by Albertson & Company was an infringement of it.

THE SUPPLY OF MOTOR FUEL

Claims That Cracking Processes Will Furnish Enough for Years to Come.

"The market value of synthetic gasoline produced by cracking in the United States during 1917 will be sufficient to supply the navy with ten superdreadnoughts. In other words, one-fifth of the 3,000,000,000 gallons to be produced will be made by cracking," said Walter F. Rittman in a paper read before the recent meeting of the American Chemical Society at Kansas City.

"By July 1 of the present year there will be in operation in the United States 4,000,000 automobiles. Financial men, in considering the investment value of motor stocks, have for several years been dwelling upon the saturation point, but, despite this consideration, the demand for machines still keeps well ahead of the forty per cent. average yearly increase of past years. When the saturation point will be reached nobody knows. Responsible and successful automobile men maintain that the present increase in rate of production will keep up for years, and that after the present high prices of materials the price of cars can be so reduced that every family having an income over $1,000 may own a car.

"On this basis the United States will have in the neighborhood of 10,000,000 automobiles—two and one-half times the present number. Assuming an annual life of five years per machine, 10,000,000 cars means an annual replacement number equal to 2,000,000; i. e., our present rate of production. When one questions the correctness of the opinion of the automobile man who suggests the above figures the answer is made that every prediction which the automobile man has heretofore made has been too conservative. An important consideration is the greatly increasing number of motor trucks necessary to replace the shortage in horses. As to the influence on this industry of the United States' entrance into the European war time will tell.

A Leading Industry.

"Only the steel, lumber and clothing industries exceed the automobile business in importance today. Detroit, the center of this new industry, has risen as a manufacturing center from sixteenth place in 1900 to sixth place in 1914. In the United States over five hundred factories are today engaged in making different types of automobiles, and new companies of varying stability are announced each week. As a side light, it is interesting to observe the approximate annual upkeep involved in America's automobile bill, which is as follows:—Gasoline, $500,000,000; tires, $500,000,000; accessories, $300,000,000; garage hire, $150,000,000; repairs, $150,000,000.

"The number of automobiles in use in this country on January 1, and for the period of the last fourteen years, with estimate for 1918, is as follows:

Year.	Number of Cars.	Year.	Number of Cars.
1905	85,000	1914	1,253,875
1910	400,000	1915	1,754,570
1911	600,000	1916	2,225,000
1912	677,000	1917	3,250,000
1913	1,010,483	1918	4,750,000

"However, gasoline requirements are not limited to the above automobiles, but in addition tremendous quantities are exported, are used in motor boats, motorcycles, farm engines, chemical manufacture, cleaning establishments, &c. The requirements per machine per annum vary with different users, some using on an average of less than a gallon a day, whereas the public vehicle often uses as high as ten gallons a day. Statistics would indicate that the average consumption per car per annum approaches five hundred gallons.

Fuel Problem Important.

"Of the various problems confronting the automobile industry the motor fuel problem of the future has loomed up as the most important, but it would seem that this problem will, temporarily at least, be solved. Much discussion and attention is paid to the use of gasoline substitutes, such as alcohol, benzol, gasoline from natural gas, electricity, &c. All of these materials are very valuable sources of power, and the extent of their use is entirely a question of quantity produced and price. Alcohol is commercial when gasoline exceeds thirty-five cents a gallon. The price, however, is based on ante-war prices, as every one realizes that the present price of alcohol makes it prohibitive. Benzol, when mixed with gasoline, makes a superior type of motor fuel, and here again it is entirely a question of the supply available.

The figures of the best informed persons in this field indicate a supply of benzol and light oils available equal to 100,000,000 gallons, which, it is observed, will fulfill less than ten per cent of our motor fuel requirements, even though none of the benzol and similar materials were used for explosives and other chemical purposes.

"Casing head gasoline (gasoline from natural gas) is an item of considerable importance because it is so volatile and has such wide explosive limits that it can be blended with naphthas and thereby make available for motor use materials which were not available. The production of this material has been as follows, but this production, it may be remarked, will hardly supply more than one-tenth of our fuel requirements:—

	Gallons.		Gallons.
1911	7,425,839	1915	65,364,665
1912	12,081,179	1916	125,000,000
1913	24,060,817	1917	200,000,000
1914	42,652,632		

Steamer a Help.

"Much is heard of the kerosene carburetor, and the Patent Office holds thousands of carburetor patents. Professor Lucke, of Columbia University, rightly believes that in the development of a commercial kerosene carburetor, it will not be a new invention, but a matter of design utilizing parts from various patents or designs already developed that will solve the problem. Practically no consideration has been paid to what is perhaps the most important factor militating against the use of kerosene, i. e., the question of explosive limits. This will be discussed later. The carburetors already invented surely embody all possible principles, so it would seem that from this time forward the problem is one of a design wherein ideas from different carburetors are brought together in a new form. A partial way out of the difficulty may be reversion to the steam type of automobile, in which heavier oil is used to generate the steam.

Digitized by Google

"The increase in the crude oil production of the United States during a period corresponding to the automobile figures previously given is shown as follows, in barrels of forty-two gallons:—

1905	134,717,580	1913	248,446,230
1910	209,557,248	1914	265,762,535
1911	220,449,391	1915	281,104,104
1912	222,935,044	1916	292,300,000

"The production of gasoline, also in barrels of forty-two gallons, has been:—

1904	6,920,000	1914	34,915,000
1909	12,900,000	1915	41,600,000
1916	54,760,000	1917	*70,000,000

*Estimated.

Increasing Supply.

"From these figures it will be observed that during the period from 1910 to 1917, when the number of automobiles increased eightfold, crude oil production grew but a little over one-third, and gasoline production increased four times, an order of magnitude comparable with the growth in production of automobiles. This increased production of gasoline from a relatively constant quantity of crude oil is obviously the result, first, of taking a larger portion of motor fuel from the crude oil and calling it gasoline, and, second, of producing gasoline from heavier oils by cracking.

"The question naturally arises as to how much further into crude oil the petroleum man can cut in order to increase the supply of motor fuel. We have all observed the Baume gravity of gasoline decrease from the seventies to the fifties, which means an increase in the specific gravity from 0.700 to 0.778. But practical motor men today believe that with the present automobile carburetor and engine gasoline containing heavier portions of the crude oil below 50 degrees Baume does not work efficiently.

"Scientific explanation of the fact can be found in a consideration of the explosive limits of various hydrocarbons. For every mixture of hydrocarbons and air, as is produced in the carburetor, there is a proportion below which the mixture contains too small a percentage of hydrocarbons to explode. Between these two limits is the desired range in which the proper explosive mixture is formed. For instance, a mixture of natural gas and air containing below 5 per cent. of gas will not explode; also a mixture containing more than 11.5 per cent. of gas will not explode. Hence the explosive limits for mixtures of natural gas and air are between 5 per cent. and 11.5 per cent. of gas. Similarly, the explosive limits for mixtures of gasoline vapor and air lie approximately between 1 and 4-10 per cent. and 6 per cent. of gasoline vapor.

Carburetor Present Problem.

"When the size and weight of petroleum molecules increase, the boiling point is raised. In other words, the higher the molecular weight the heavier and less volatile is the material. Furthermore, as the volatility of these hydrocarbons decreases the limits for their explosive mixtures with air, below which nothing happens and above which there is a burning rather than an explosion, come closer and closer together.

"Consequently, as we go from lighter petroleum products, such as gasoline, to heavier petroleum products, such as kerosene, and up to materials boiling above 400 degrees, Fahrenheit, the range for explosive mixtures of air and heavy hydrocarbon vapors becomes more and more narrow, until a point is reached where there is a great difficulty in adjusting the mechanical parts of the carburetor so that they deliver the proper explosive mixture. For example, suppose a mixture of five per cent. hydrocarbon vapor and ninety-five per cent. of air is the only possible explosive mixture for the vapors of a certain substance, how difficult, if not impossible, it would be to adjust a carburetor to deliver accurately and continuously that exact mixture.

"The result then is that when this heavy material, with narrow explosive limits, is used for fuel there is slow burning rather than explosion, and only a part of the combustion occurs in the cylinder where it can be utilized. Therefore, it is questionable whether an efficient carburetor for heavy kerosene can be devised.

Cracking Is Solution.

"Other suggested solutions of the motor fuel problem involve the use of oil derived from coal, shale, peat and lignite. These will be immensely important sources of liquid fuel in the more remote future. Passing over the large supply of light oil possible from coal now burned without coking, which may amount to as much as a billion gallons of fuel per annum, there are immense shale deposits in America containing a volume of oil many times greater than that now known. Here the problem of obtaining motor spirits from the oil will arise again, and the solution of it, as all our present problem, will necessitate cracking processes.

"Then, as now, the demand for motor spirits will run ahead of the supply obtainable by straight distillation, and the logical solution of our present motor fuel problem will be the logical solution in future problems. The fundamental proposition is that when the demand for gasoline doubles or trebles, while the amount of petroleum remains nearly constant, we must make more gasoline from a given volume of crude oil. The best evidence that this proposition furnishes the answer to our problem is the fact that cracking processes are now solving the problem. In other words, since twenty per cent. of our gasoline is now being made by cracking, the price of gasoline would of necessity be much higher without this increased supply.

"The chemical phenomena involved in the cracking of heavy oils into lower boiling oils have been discussed in considerable detail in Bulletin No. 114, United States Bureau of Mines. Broadly speaking, and without consideration of relative merits, cracking processes may be classed under the five heads:

Supply Is Assured.

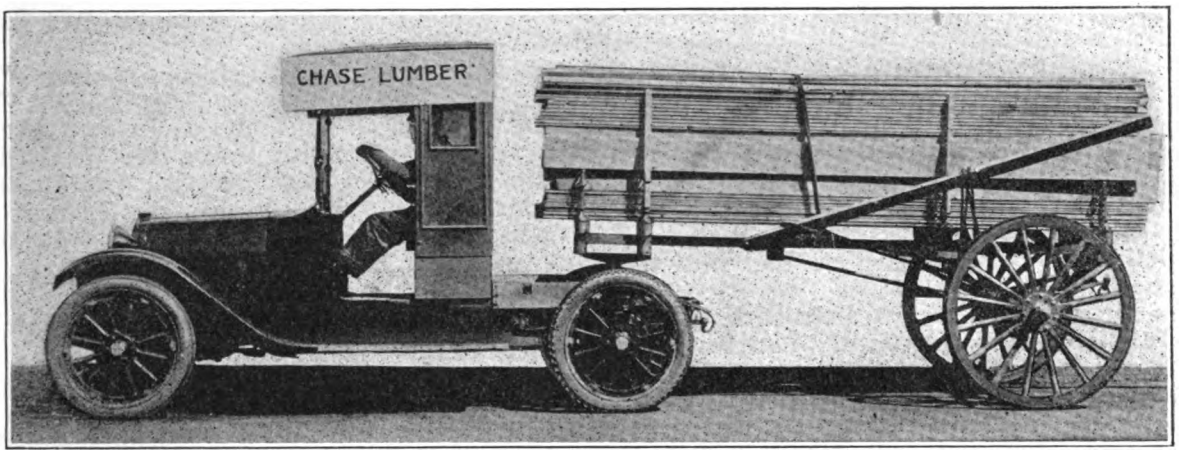
"(a) Liquid condition processes wherein oil is cracked as a liquid.

"(b) Gaseous condition processes wherein oil is cracked as a gas.

"(c) Processes wherein cracking is aided through the use of catalyzers.

"(d) Processes wherein the oil is mixed with steam, hydrogen or other materials.

"(e) Combustions of the above four methods.



"The object of the present paper is not to discuss the technical nor the research side of cracking, but to indicate how real is this industrial operation today. During the present year, 1917, approximately 600,000,000 gallons of cracked gasoline is being produced in the United States. It is estimated by competent authorities that the production of cracked

Digitized by Google

gasoline in 1918 will be 1,000,000,000 gallons, and that by 1920 more gasoline will be produced by cracking than by all other methods. Many persons have been disappointed because cracking processes have not reduced the price of gasoline materially, but they have failed to consider their tremendous benefit in keeping the price of gasoline from going to ten cents a gallon higher. Seven thousand automobiles a day require a cumulative supply of motor fuels. Our crude oil production is not increasing. Kerosene carburetors, as yet, are not a factor. The entire load is falling on the shoulders of cracked gasoline, and cracked gasoline promises to make light of its load."

From Car to Tractor.

The illustration shows a Dodge Brothers 1915 touring car transformed into a tractor by having the tonneau removed, a cab placed on the frame for the driver, and coupled with a Martin Rocking Fifth Wheel to a lumber wagon. This outfit is used by the C. P. Chase Lumber Company, Springfield, Mass. The load weighs 5,500 lbs., showing that the small car has a wonderful capacity as a tractor. If the hundreds of thousands of used cars which are cluttering up the garages of the country were put in service as tractors, using the present horse-drawn wagons, they would release the horses for the farms, where there is dire need of them at this time.

Easily Attached Tractor.

The Emerson Motors Company.

Charged with conspiring to use the mails to defraud the public, the Emerson Motors Company, Inc., its officers and directors and three subsidiaries have been indicted by the Federal Grand Jury in New York City.

The company advertised that it would furnish the public a fine car at $395. Stock was sold on the representation that a net profit of $69 a car could be realized. It was alleged that orders for 60,000 cars had already been received.

It is charged both in the bankruptcy petition and the indictment that the Emerson concern was simply a stock-selling scheme and never intended to build motor cars. More than $1,500,000 is said to have been realized on sales of the stock, and not more than $100,000 can be realized on the plant and office at Kingston, N. Y.

The counsel for the creditors say:

"The promoters got the stock for 17 cents a share and sold it to the public as high as $7 a share."

The parent company was organized in Delaware in 1916 and was authorized to issue at $10 par $3,000,000 in preferred stock and $7,000,000 in common. On August 15, 1916, the company issued a statement claiming to have $190,239 in bank. More than 252,000 shares of stock had been subscribed.

OBSOLETE CARS.

Connecting Rod Oiler.

As a general rule the upper portion of the connecting rod on an automobile is lubricated by the oil splash in the crank case, but in many cases does

not work satisfactorily, especially on an engine where the bushings are burned out, caused by inefficient oiling. The attachment illustrated has been

Digitized by Google

tried with good returns. Bore a hole in the upper part of the bearing and tap, then screw in a small oil cup, as shown, and it will be found that a constant supply of oil will stay in the bearing using this device.

HOT WEATHER DRIVING

It Calls for Increased Precautions and Care of Tires and Motor.

From H. C. Brokaw, Principal West Side Y. M. C. A., New York, Automobile School:—There are quite a number of points which should be borne in mind by auto owners with the coming of hot weather, if the most efficient service is to be had from the car.

One of the secretaries of the branch called me up excitedly a few days ago to ask why a seemingly good tire should blow out after a short run. A few minutes later another secretary put the same inquiry with variations. That is, he had a tire which was rather old, but it had been inflated for two weeks and had been running every day since inflation when it tested 80 lbs. pressure.

The first named secretary had been invited by a friend to take a ride. He watched the tires inflated and all other bits of preparedness, and saw that nothing was overlooked, and settled down for a fine ride. The blowout came about five miles away.

The trouble with both was that they had not taken into account the fact that summer is at hand. Experienced drivers know that in hot weather it is not possible to drive their cars with so high a pressure on the tires as they have in winter.

Considerable heat is generated by rolling a tire over the ground. This heat expands the air in the tire and increases the pressure. In the winter this heat is absorbed to a large extent by the cold atmosphere and the cold and wet pavements and therefore the pressure does not vary so much. In the summer the roads are very hot, the air temperature is high and the heat generated by friction is not carried off to any appreciable extent.

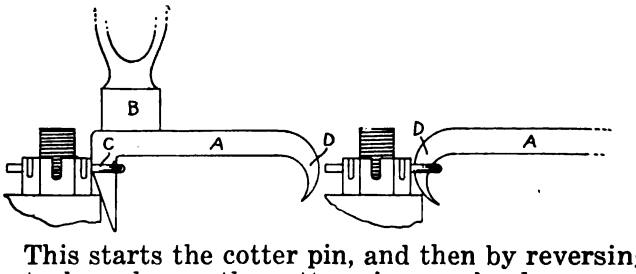
On a trip last summer I noticed that the car was riding harder than usual and a test of the pressure on the tires developed the fact that it was above normal. To find out just what the difference in pressure was, we tested it before leaving the garage next morning. We found after rolling about forty miles at an average speed of thirty miles an hour, that the pressure had increased about twelve pounds.

I know that several of the tire manufacturers instruct users not to carry less pressure on the tires in hot weather, saying that the increased pressure due to heat is not sufficient to materially affect their make. This is probably true for new tires, or for about two-thirds of their guaranteed life, but if the tire has been weakened, through having been run under inflated, or from fabric deterioration through cuts in the tread, then I believe there is danger from the increase in pressure due to heat.

More tires are damaged by under inflation than by over inflation, because the former breaks down the side walls through running flat in practically every case, while the over inflation causes a blowout only when the tire is weak at some point. It would be good practice, however on hot summer days, to leave the garage with the tire pressure about ten pounds less than that specified by the manufacturer as being correct for his make. Any driver ought to test out his tires after running at a good clip on a hot day and find out just what they do. A little patience would enable him to understand how much his tires heat up and he could regulate the pressure accordingly.

There are some other hot weather points which it might be well to keep in mind if one would get the best results from the car. One of these is the care of the carburetor. It will be found usually that not quite so much gasoline is required as in cold weather, and therefore the dash adjustment may be carried a little nearer the lean, or air, side. This not only saves gasoline, but increases the power of the motor.

It will be found also that in most cases the hot air stove of the carburetor may be dispensed with or adjusted. Usually provision is made on the hot air stoves for allowing some cold air to enter, or to take cold air entirely. Where the carburetor is water-jacketed, there usually is a valve that may be closed to prevent the flow of hot water. Experiment will determine whether it is advisable to cut out the heat entirely on the individual carburetor, since all are not benefited by the change.



If the fan has been disconnected, or the radiator covered up, these things will be corrected, of course, when hot weather comes along. The engine naturally runs hotter in the summer time, the water vaporizes faster and occasionally boils away, so that it is necessary to inspect the radiator more frequently to see that the water is not running low.

Likewise the water in the storage battery will evaporate more quickly and where it has been necessary to replenish it once in two weeks in the winter, it will need to be done every week in hot weather. This is not entirely due to evaporation from heat, but is accounted for in part by the fact that the engine starts easier and therefore less current is used for starting, and there is more daylight and the lamps are used less. Therefore the battery is more often in a fully charged condition and the charging current causes more gas than usual. This is caused by chemcial action which decomposes the water, the hydrogen and oxygen gases passing off through the vent holes; the water escapes from this cause as gas instead of vapor.

In hot weather city streets are generally sprinkled regularly and the country roads are oiled some time during the season. The novice going behind a street sprinkler or reaching an oiled stretch of road, should exercise particular care to prevent skidding, as he would be unlikely to realize the danger unless he has experienced it once.

Cotter Pin Remover.

An easy way of removing cotter pins is shown in the illustration. Make a tool, A, of some hard metal. Insert it as shown and tap it lightly with a hammer,

B. This starts the cotter pin, and then by reversing the tool as shown, the cotter pin may be drawn out by means of the hook, D.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

Happens Too Often.—A car entered the town of Hollidaysburg, Pa., not long ago at a high rate of speed. It got beyond the control of the driver, dashed into tree and the four occupants were hurled out, two to their death. The affair was simply a Sunday evening's ride for "pleasure."

Blowout of a Rear Tire.—At Sharon, Pa., a car was being driven at about 45 miles an hour when a rear tire blew out. This hurled the occupants out, and one was killed and four seriously injured. When a car is being driven at 45 miles an hour a tire is liable to blow at any instant and it requires a good combination of road surface and expert driving to avoid overturning.

Three Persons Killed.—A man stopped the car he was driving at Mansfield, O., to allow a freight train to pass, but failed to note the approach of a passenger train from another direction. The car was smashed and three persons were killed.

Charge That the Driver Was Drunk.—On Staten Island, N. Y., five men were hurt and may die as a result of a car having been run into a telegraph pole while going at high speed. The driver is charged with drunkenness. The machine was smashed.

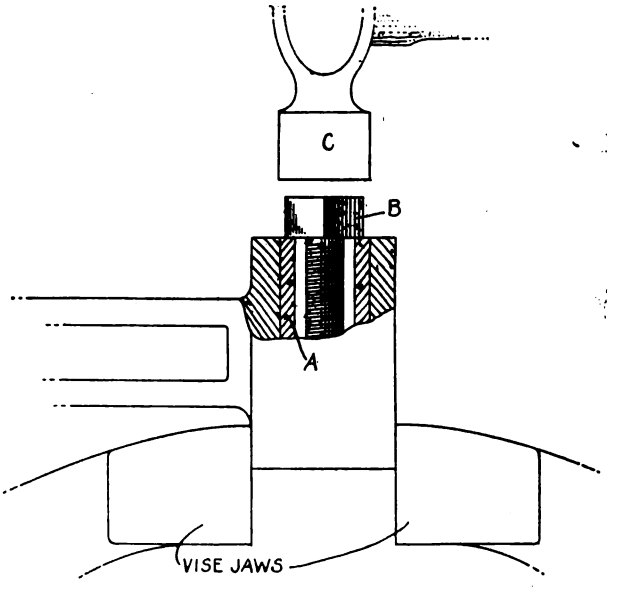
Two Young Women Die in a Wreck.—A party of young women were driving a car in Clarksville, Miss., when they suddenly came upon a bridge at right angles to the road. This disconcerted the driver who suddenly threw on the emergency brake. The car overturned and all the occupants were pinned underneath. Two accomplished and attractive young women were killed and all somewhat injured.

Whirled to Death.—At Newton, N. J., a man was whirled to death on an automobile wheel, a local doctor stating that he must have died after the first dozen revolutions. He probably got his foot caught in the spokes in some way unknown. The supposition is that he became confused while crossing the street and made an awkward movement to avoid being struck, inopportunely thrusting his foot between the revolving spokes. The car driver did not hear the victim's cries as he banged along like a flail, but put on more speed as his attention was attracted by the shouts and gestures of passers-by.

Driver Fell Asleep.—In Fitchburg, Mass., an automobile was wrecked by being driven into a stone wall. The driver frankly admitted that he fell asleep. He said he has been driving a great deal during the last few days and has had very little sleep. He was overcome with sleep very suddenly for he did not feel it creeping upon him, and the time that elapsed between his looking at the speedometer and his crash into the wall could not have been two minutes.

Three Killed and Four Injured.—Near Harrisburg, Pa., three were killed and four injured when a car skidded and ran wild. The machine struck a small concrete guard at the side of the road, plunged sideise into a telegraph pole and then into a concrete ridge and still continued a short distance up the road. The two women who were in the back seat were crushed and thrown from the machine. The entire rear end of the machine was demolished and torn from the body.

Three Lives Blotted Out.—At Allentown, Pa., a car struck a mud puddle, skidded and overturned. Three of the four occupants were killed, and it took the only one left 20 minutes to extricate himself from the car and go for help. The men were returning from "an anniversary of a cafe."

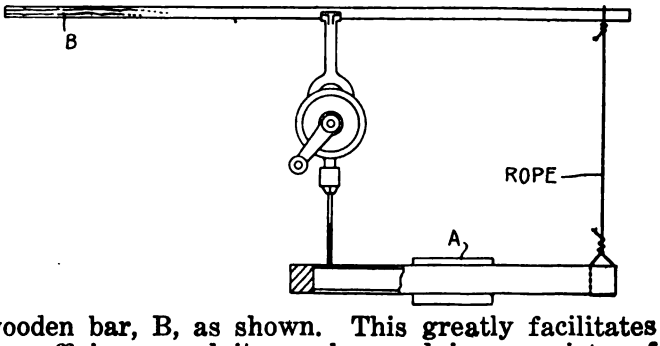


Probably a Case of Remorse.—A young man was driving a car in which was his friend when he lost control and the car overturned pinning the passenger beneath it. The driver reported the accident and then suddenly vanished. It is not even known whether or not he was injured in the accident, and inquiries have been made at all the hospitals near by, on the supposition that he had gone to one of them for medical attention. His disappearance is not understood by either his relatives and both families are apprehensive regarding his safety.

Car Falls Into a River.—A sharp bend in the road near Moline, Ill., caused a car travelling at a rapid rate to leave the road and go over a high embankment into the Mississippi river. One person was killed and four badly hurt. The car turned twice over and pinned its victims beneath it.

Crashes Into a Railing.—In New York City a car crashed into the front fence of a house, breaking the front wheel and the mudguard. Five persons had been run down by the reckless driver who attempted to run away when he found the injury he had done. He was caught by a policeman.

Ford Car Spindle Bushings.



A method of removing Ford car spindle bushings,

A, is to place a 3/8-inch crank bolt, B, in the bushing and tap lightly with a hammer, C, as shown in the illustration.

A Hand Drill Device.

To secure an increased pressure when using a hand drill on a steel wheel, A, bear down on a

wooden bar, B, as shown. This greatly facilitates the efficiency and it can be used in a variety of cases.

THE LAW OF PRICES.

The city of Detroit, Mich., is reported to be waxing strong and flourishing like the proverbial "green bay tree," its growth being due to its automobile manufacturing business. Nor does the phenomenally high wages paid there seem to put a damper upon its prosperity, contrary to the usual claims of pseudo-economists who would like to have it appear that high wages are a hindrance rather than a spur to prosperity, although all they have to do to prove they are wrong is to find out the wages paid in the more prosperous and in the more destitute countries of the world.

Now that so many male workers are being taken from ordinary industries and transferred to the work of war, their places are being filled by women and with far better results than would be generally imagined. This naturally brings up the old and trite remark that when "women do the same work as men they should have the same pay as men." And so they should and would if conditions were such that women could sell their labor at their own figure, or at all events, as near their own figure as owners of merchandise sell their goods; or even if they were sufficiently forehanded to withhold selling their labor until some employer were obliged to pay their price for it.

But the conditions of the purchase and sale of labor have never been fully understood, or perhaps acknowledged, for it is not difficult to understand them. The remark is often made, for illustration, that women school teachers should be paid the same as men for similar service, and so they should of course, if they could get it. The writer of this would be glad to see hard working and competent editors getting as much as third rate prize fighters or ordinary outfield players on league base ball teams, but alas and alack, this is not the case. He would like to see a country minister get as good salary as a bartender at any of the Broadway lobster palaces. He would rejoice to know that the washer woman who faithfully scrubs clothes were paid as well as, say, the inefficient public stenographer at the hotels.

In fine, he would be glad to see that all were rewarded according to their efforts and not according to the rate of pay in open market, for that would indeed be in accord with exact justice and not with either normal or abnormal conditions. Take the case of the present high prices for most commodities. Owners of such commodities are undoubtedly making unduly large profits upon them. They exact such profits simply because the demand far exceeds the supply. No matter what the need of the purchaser, he must pay possibly twice as much as it costs to produce them.

It is this condition that leads to the discussion, pro and con, of government control of prices as relates to food and other commodities. But if the owner of food products has no moral right to exact more than they are worth simply because the supply is less than the demand, and it is advisable that the governments should step in and fix the prices he must ask for them, why not fix prices upon all commodities upon which exorbitant prices are charged simply because the demand is greater than the supply? It is true that it is perhaps more important than in the case of anything else that people purchase the food they eat—their very life—at a fair price; and next in importance is that those who have labor to sell—the only commodity they own—should get a fair price for it. But having begun this government price fixing, and the overturning of the great natural law of supply and demand, why should we not have all prices fixed for us?

This would undoubtedly be objectionable to workers who, as we understand, are getting $12 a day in Detroit for trimming automobile bodies, but it would be quite satisfactory to their employers. It would be objectionable to employers who can buy labor at absolutely their own figure, but would be hailed with delight by their workers. So likewise women who according to that same law of supply and demand are obliged to work for less wages than men when doing the same kind and amount of work would be glad to have some legal mandate in force compelling the same pay for women as for men. But whether or not government control of prices is favored depends very much upon "whose ox is gored." Those who have something to sell would be glad to have government price-fixing to the extent that nothing should be sold below a certain figure, and those who have something to buy want prices fixed to the extent that nothing should be sold above a certain figure. Yet the principle is the same in the one case as in the other.

Of course, price-fixing is a transgression of the great natural law of supply and demand, which in our opinion should never be violated except as a temporary and pressing expedient to correct a most abnormal situation. It is far better to change supply and change demand than to over-ride them

Digitized by Google

In the case of producers of food and of manufactured products the corrective has always been to raise less—produce less—and in some instances to destroy that already produced in order to secure a fair price for the balance. Labor has a far wiser and more just way to correct the evil of over-supply; it simply advocates a reduction of the hours of work, believing, and justly, that leisure is better than enforced idleness. Of course, without let or hindrance, this would be carried too far, just as it has been in Russia, where half-blinded workers suddenly impressed by their own power and with a keen sense of their own past wrongs, have simply made idiots of themselves. They have got the rope in their own hands, and now they are disposed to hang themselves with it. So likewise, owners of commodities in this country in many cases are not satisfied to charge a fair profit on the increased demand and decreased supply of the products they own, but raise the price beyond reason and justice, and even where such products do not stand them at higher prices.

We are quite well aware that the foregoing solves nothing and "gets nowhere," but if it serves to set people to thinking in the right direction it will aid in the correct solution of pressing problems such as have never before confronted civilization.

STREET CROSSING DANGERS.

Much discussion is going on as to how to remedy the congestion and delays at the street crossings of the great thoroughfares in New York City. There is but one practical way to eliminate this evil, and that is to put foot passenger viaducts over the streets not only at crowded crossings, but between street intersections where the traffic is heavy. These might be wide enough for six persons to walk abreast over each crossing where the congestion is greatest, and perhaps of sufficient width for four persons to walk abreast midway between crosswalks. These would provide ample means for crossing the streets without disturbing or delaying vehicle traffic in the slightest. Of course, the ascent and descent on such crossings would be objectionable to the aged and infirm, but so likewise at present is the necessity for hurry and the danger of crossing the streets at grade.

As for the comparative time consumed in crossing the street at grade and by way of an overhead bridge, the blocking of traffic at intervals is far more disadvantageous and time consuming. The cost of such bridges need not be heavy, and in these times of fast moving automobiles and commercial cars, the street vehicle traffic could afford to bear the expense of construction and maintenance and still be gainers. The holding up of vehicles at so many crossings in the city at present consumes more valuable time than that required for the entire trip otherwise.

In addition to this, the saving in police traffic duty would be much. The police force of New York City has never before been so efficient and satisfactory as it is today, but if many of the traffic members of the force could be transferred to regular duty conditions would be still better.

Vehicle accidents are increasing according to official reports, but they might be much reduced if pedestrian traffic were confined to the sidewalks and bridges, thus relieving automobiles and other vehicles from a most vexatious responsibility.

These street viaducts must surely be adopted sooner or later. Why not put them in over the main thoroughfares at once?

ELEMENTS OF TAXATION.

The war tax should be the same on one article of use as on another. If automobiles are to be taxed, all other vehicles should be taxed at the same rate. And if vehicles are to be taxed, so should other articles of necessity or convenience. This making meat of one thing, fish of another and fowl of a third, is both unwise and unjust.

Not that as far as we have learned there has been any objection to the tax on automobiles on the part of their owners. Those who own and use automobiles are as a rule up-to-date and progressive, and they are thus naturally willing to contribute their share of the expense necessary to secure the quick and successful conclusion of this war. Indeed, this is the apparent general feeling. But there is naturally an aversion to a levy of a certain per cent. of tax upon this thing, a less tax on another and perhaps a still greater tax on another. A man may be able to own an automobile and barely able to own it; it may be about all he owns in the world and vitally essential to the support of his family. Another man may be well off in this world's goods and yet not own one. Is it reasonable or just to penalize the car owner for getting his living the way he does, or to reward some one else for not owning a car?

After all has been done and said, there is no better method of imposing taxes than that laid down by Adam Smith, namely: "Equality, certainty, convenience and economy." As further elucidated by Mill and others, "equality of taxation means equality of sacrifice," although it is generally admitted that this standard cannot be fully realized. The other three conditions of course refer to tax collection.

Although it must be freely admitted that our lawmakers naturally find it difficult to suit everybody in the imposition of these war taxes, they seem to have thrown the settled convictions of political economists to the four winds of heaven, so to speak.

THE LIBERTY BONDS.

For those who are not fully conversant with the facts in relation to Liberty Loan Bonds, it may be stated that the first issue of $2,000,000,000 is to bear date of June 15, 1917, and are to run 30 years, unless the government exercises its right to pay them 15 years after date. They bear interest at 3½ per cent. per annum, and the interest is payable semi-annually on the 15th day of December and the 15th day of June each year.

These bonds are nontaxable. If your city, county and State taxes are three mills on the dollar, a not unusual tax, these bonds are equivalent to ordinary corporate bonds or other investments bearing 6½ per cent. In addition, no Federal tax which war conditions may later make necessary will affect them. The only tax these bonds are subject to is the inheritance tax, which applies to all property of all kinds.

There are two kinds of these bonds. Bearer bonds are to be issued in denominations of $50, $100, $500 and $1,000. These are made payable to bearer, have interest coupons attached which are detached by the holder when the interest installments they represent are due, and can be cashed at any bank the same

Digitized by Google

as a United States Treasury note. Registered bonds are registered as to both principal and interest, in denominations of $100, $500, $1,000, $5,000, $10,000, $50,000 and $100,000; checks for the amount of interest due will be mailed out semi-annually to the holders of these registered bonds.

A special advantage no other bonds, National, State, municipal or corporate, have is that if the United States during the continuance of this war shall issue other bonds at a higher rate of interest, the holders of these Liberty bonds have the right to exchange their bonds for bonds bearing the higher rate of interest, dollar for dollar.

Blank forms of application for the purchase of these bonds can be obtained from the Treasury Department, any Federal Reserve Bank, any National, State or private bank, any express office, and any post office in the United States. Any bank or postmaster will aid applicant in filling out his blank and the other acts necessary to obtain these bonds.

It is predicted by those best able to form an opinion, that these bonds will soon be selling at a premium. We know of no other United States bond issue in the past bearing similar interest and of the same character, that has not sold at a premium before maturity.

Of course, the outcome of this war cannot be doubted for an instant, and it should not be necessary to urge in the slightest the purchase of such bonds by those who can afford to do so.

WOMEN.

No better evidence need be had that a woman may not only be able to drive and handle an automobile as well as a man, but that she can safely be depended upon to judge a good car, either new or second-hand, than the article by Mrs. A. Sherman Hitchcock which will be found on another page. Incidentally, it may be remarked, it also reveals the fact that the fair sex knows how to write comprehensively on this subject without using a single superfluous word or a word that does not clearly express the right meaning. Mrs. Hitchcock is one of the pioneer drivers and car owners of the country. That women may well be proud of her goes without saying, and as no improvement or merit in either sex can possibly be confined to that sex alone, the male sex should be equally proud to know that her talents as an automobile expert are of the highest. By the way, and along something like the same line, who can estimate the exalted and effective part woman has taken in this world war? She has abundantly proved that she can do much that no one ever dreamed she could do that men have always before done, and in personal sacrifice and heroic deeds many noble things that men have no bent or inclination to do. Surely, it is time for those who have always been opposed to women taking an active share in government to revise their opinions.

PRICE AND VALUE.

With the enormous rise in the price of almost everything that goes into the making of an automobile, it is little short of amazing that manufacturers have not more generally raised their prices. Under the present conditions and prices the profits must be far less than two years ago. As a rule those who have things of any sort to sell are ready to seize upon any plausible excuse for raising prices, and automobile manufacturers are thus most commendable exceptions. We believe they will be compelled before long to raise prices to a marked degree and that intending purchasers should not hold off any longer than necessary.

In the case of most things of necessity or convenience prices have been raised beyond all reason. The grocer raises the price of tea and coffee on the ground of "the war tax," when such a tax has not yet been levied. The tailor pays $2 more for the cloth of a suit of clothes and immediately raises the price $10 to the consumer. The shoe dealer has raised prices beyond all sense or reason, in some cases as much as 100 per cent. The cigar dealer pays $1.50 more per thousand for cigars—an increase in cost of about one-seventh of a cent each—and immediately raises the price one or two cents each to the consumer. Thus have prices been raised unnecessarily all along the line with the exception of the automobile which really has not been advanced in price as much as the situation warrants.

Price conditions that now prevail well deserve the consideration and study of those who are interested or vitally concerned in economics and trade. They show how quickly price and value part company when demand and supply are so unequal, and how utterly untrue it is that the cost of production has as much influence upon prices as demand and supply inequality.

THE IMPORTANCE OF PUBLICITY.

One of the officials of the Olds Motor Works marvels at the fact that the vast army of hundreds of thousands of workers now employed in the automobile industry was secured without any apparent injury or reduction in the ranks of other industries. He says that "if through any miraculous circumstance the bottom should suddenly fall out of the automobile industry and its army of employees was forced to find employment elsewhere, it would create a most most serious situation and disrupt labor conditions generally."

This is all quite true and important. It leads up to a trend of thought that political economists and business men should not fail to grasp. Clearly, the reason why it has been so comparatively easy to obtain workers for this great automobile industry—foundrymen, engineers, machinists, textile workers, mechanics of all kinds, together with salesmen, clerks and common laborers—is because efficiency in production is constantly increasing and at a much faster rate than the natural increase in consumption. The best proof of this is the imperative necessity for advertising so that the market may be stimulated to consume as much as can be produced.

And not only is advertising the best means of stimulating the much needed consumption of products, but it is by far the cheapest and most economical means of doing this. It abundantly justifies its existence. Take away this practically only means of letting the public know of the new and useful things that may be had to supply their needs, and consumption would decrease at least one-half, while periodical literature would lose much of its interest and value.

Yet in spite of this fact some of our public men seem to be busily engaged in the advocation of belittling and hindering advertising, and thus doing all

Digitized by Google

in their power to increase enforced idleness, close factories, and to impede the public welfare.

A BURSTED BUBBLE.

It appears that more than 15,000 persons put their savings into the defunct Emerson Motors Corporation expecting to receive 20 per cent. profit, their purchases amounting to something like $1,500,000, while the tangible assets are about $150,000. We received a good many letters from readers asking our advice as to making an investment in the stock of this corporation, but they were recommended not to do so. Neither did we accept the flamboyant advertising of the concern. The outcome was as we expected.

Those who are solicited to invest money in new enterprises, either to be or about to be, which are located so far away that it is inconvenient or impossible to make a thorough investigation into the character of the promoters and the truth of their claims, would do well to follow one of the old whist rules—"When in doubt, don't." Opportunities for investment with the probability of great returns are indeed rare in this day and generation. Any business enterprise that after full investigation gives evidence of large profits need not languish for want of capital, nor need any plausible project suffer from failure to get some one to investigate it. In all the great money centers there is plenty of capital awaiting profitable investment. But capital is invariably timid, and must be shown.

Not many years ago enterprises of real merit suffered from the inability of their promoters to secure the necessary capital to launch them. The telephone was a case in point and many others might be cited. But that was before the days of big massed capital and a ready means of enlisting investment.

A WORD OF CAUTION.

Our readers are warned against organizations of various kinds which have sprung up in different parts of the country, often calling themselves clubs, with a small yearly sum as dues—perhaps $3 or $5 or $10—which pretend that they can save car owners considerable money on the purchase of various automobile accessories and supplies, including gasoline. One of these organizations, we understand, was stopped by a fraud order from the Post Office Department not so very long ago. We advise our readers to fight shy of every concern of this kind that appeals to them for money in the shape of dues.

Four Valve Cylinders.

A reader asks what is the advantage of more valves than two in the cylinders. In reply it may be stated that many are enthusiastic as to the idea of having four valves in the head of a cylinder. The claims are made that with four valves in a cylinder they can be made small and thus are much more easily handled when it comes to grinding. The springs are lighter and the valves run much longer without requiring attention. If combined with a detachable head one has an exceedingly accessible engine, the head can be machined all over inside, and an overhaul of the valves, besides being required at less frequent intervals, can be carried out under almost ideal conditions on the bench and altogether apart from the engine itself.

SOME SHORT CUTS.

Pointers the Garage and Repair Man May Find Convenient.

From J. N. Bagley, Nebraska.—Hardly a day passes but the wide awake mechanic will find some short cut method of doing a piece of work or to make a special tool for a special job. Many times these tools can be made of otherwise useless scraps and when it is finished the outlay consists of nothing but a little time. In many instances the tool made will excel one that can be purchased for the same work. There is a saying that necessity is the mother of invention, and it is more true than ever at this day and age of the world.

If every mechanic who has some little kink would send it to some trade journal it would be appreciated, of course, and the readers would profit greatly by it. I happened to call upon a brother mechanic one day not long ago and he made a little device for a special difficult job that he had to do and I asked him why he did not send a sketch and description to the trade journals so that others who were engaged in the

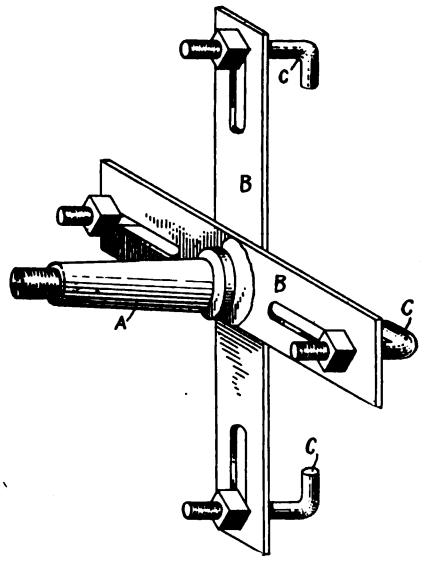

Fig. 1.

same line of work, could profit by it. His answer was something like this: "If they want to find out let them do like I have, figure it out for themselves." Now, this did not appeal to me as the right sort of spirit, so I asked him: "Do you take any trade journals?" "Yes", he replied, "many of them." "Do you get a great many useful kinks out of them as you read them from time to time?" "I sure do", was the reply. "All right; do you consider it fair that other mechanics contribute for your good when you do not feel that you should give your ideas in return? Isn't it a matter of fact that many of their short cut methods are just as good as yours and you are getting the good of them?" He stopped for a moment and fingered a small greasy six-inch Crescent wrench, finally remarking: "I guess you are correct; I'll just send in some of my shop helps for it is no more than right."

Any amount of good can be exchanged in this manner. I do not see a single man who does not take a great interest in shop kinks. In fact they are the first things they turn to after getting the magazine, but many of them are too busy to take the time to contribute. Take time, boys, and help to make the

Digitized by Google

trade journals better for the masses. The editor is striving to get a paper that will do the reader the most good and a co-operation of the interested readers will help him greatly to attain his desired end.

There are a number of instances where the dealer is called to the country to get a car with a broken axle. In this instance it is necessary to have some sort of device with which to handle the car. In many cases the dealer has a device which he has purchased for the purpose and then again there are a number who have nothing to use for work of this sort. The little device shown in Fig. 1, will answer very well for towing light cars and can be made by any one having a little ingenuity and a few tools. Take a spindle from some old car and make a cross as shown at B, each of the arms having a slot in it to allow of adjustment of the lugs C. The lugs should be made so that when the nut is tightened on the back side they will grip the outer flange of the housing. The wheel may be slipped onto the spindle and the car towed in very nicely. A wheel can be used with the outfit and there is no risk to run in the wheel from some other car fitting. The wheel can be supplied with an old tire that has practically no value and will make towing easy.

In Fig. 2 we have a very useful device which can be made from scraps picked up from time to time around most of the shops about the country. It is not necessary to enter into any lengthy article

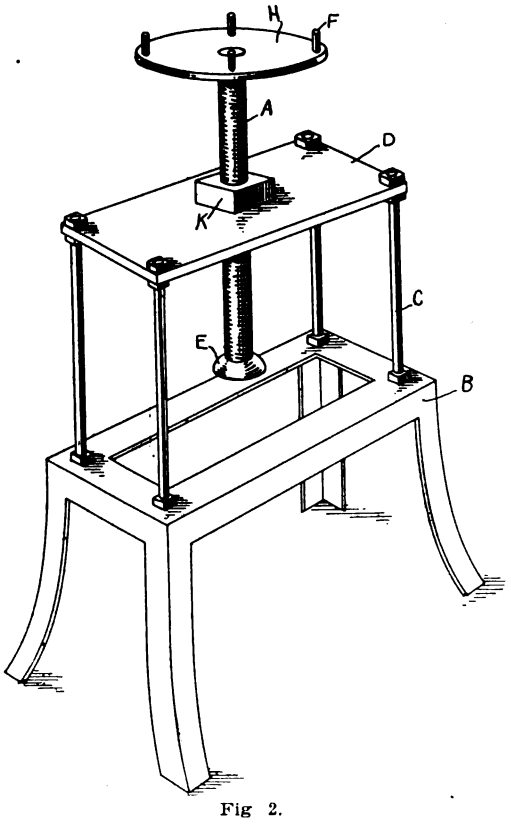

Fig 2.

giving the uses of a press, for at this stage of the repair business every man knows the value of it in the shop. The one shown in the drawing is made from scraps and answers very well. The base B is a stand from an old discarded cream separator which can be picked up nearly every day. The wheel H at the top and the screw A at the top are parts of an old cider mill. The rods C, supporting plate D, carrying the screw, are made of ¾ inch rods and made secure to both top and bottom with double nuts, that is, one on either side of the plate. To permit of a heavy enough plate being at the top to handle the screw, the block of metal K is placed at the top with a large hole in it, in case there is no way to cut the thread for the screw. Now place

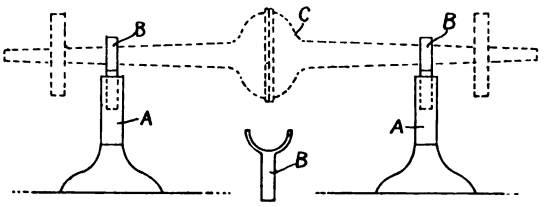

Fig. 3.

the screw A in position and with melted babbitt, run it into the opening. This will answer very well for the threaded passage for the screw, and when it becomes worn sufficiently to cause trouble, it can be replaced with a new babbitt in a few minutes. In most instances for light work the wheel A at the top can be turned with the hands, but in case the work is heavier and requires more pressure than can be applied in this manner, a bar can be slipped between the lugs F and sufficient pressure applied to get the desired results. It is a very good plan to lace some sort of swivel arrangement at the end of the screw at E, to prevent the end of the screw from turning on the shaft or the work being handled.

In Fig. 3 we have a very simple device which is made from old parts about the shop—discarded housings from the rear axle, as shown at A. Make a couple of U-shaped yokes that will slip down into the housings as shown at B, and the device is ready for use. This comes very handy for supporting rear assemblies while taking them down and putting up, as shown by supported assembly C. I have also found that this same device can be used to a very good advantage for placing shafting out of the way. As the lengths of shaft grows shorter the stands can be moved closer together to accommodate shorter pieces.

A Good Word for Two-Cycle Motors.

From Charles E. Duryea, Pennsylvania.—J. F. Springer's remarks on the type of engine contain the usually accepted facts all right, but some of the statements made without explanation leave the wrong impression in the mind of the man who does not know. The usual 2-cycle engine is used for boats where full power is demanded from start to stop. Running at full power a 2-cycle usually sends some of the fuel over the deflector and out into the exhaust unburned. This is of course wasteful But for shop and auto use the engine should not be so small as to be worked at full power except when an occasional emergency demands. A steep hill or deep mud or grinding and wood sawing at the same time, for example. At part power no fuel gets away and since the 2-cycle uses constant compression, it is more economical than the 4-cycle which is notoriously wasteful at low compression (part power). The 2-cycle cools better because it holds the hot gases for a less proportion of the time and so can be run hotter. It gets more internal cooling which saves heat. It has far less friction and so saves fuel on this account.

That it is slightly more sensitive is true. An engine builder only last week told me that he did not

Digitized by Google

like a ball bearing crank shaft to a 4-cycle engine because it made it run so free that the carburetor had to be beautifully regulated or it would not idle well. This is one complaint with a 2-cycle. It can be remedied by adding a load of some kind or cutting out the feed to one or more of the cylinders.

Back firing is likely with large transfer passages and lean economic mixtures, but it is easily stopped by proper screens. Too often the 2-cycle has been made hastily, but with equally good workmanship it is a better engine than the 4-cycle for usual auto and stationary work. Its design cannot be bad, for it depends on design rather than on added parts for the desired result.

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

2159 He Wants to Know Much.

From S. C. Kauffman, Colorado.—As I am a subscriber to your magazine, I would like to ask a few questions through the same. We have a Royal, 35 H. P. car, manufactured by the Crow Motor Car Co. This spring we installed a Bosch high tension magneto and a Schebler model R carburetor, which helped it very much. Still I do not think we are getting the full benefit of the 35 H. P. The car has run about 15,000 miles and the valves have been ground recently. Why do we not get more power? Some people claim that only 10 per cent. of the actual power produced by the engine ever reaches the rear wheels for use. What is the reason that it is lost? I think it is due to friction. Others also claim that a counter balance crank shaft gives more power to rear wheels. How is it constructed? How does it tend to eliminate friction. Would a magneto and Prest-O-Lite system be more satisfactory and cheaper than a dynamo and storage battery for ignition and lighting purposes on a motorcycle which now uses dry cells for ignition and has no lights? If you can give me some information it will be appreciated.

Reply.—Lack of power may be due to so many causes that a volume would be necessary to cover them all. The apparent lack of power in your case may be caused by too high a gear. Cars are sometimes geared for high speed on level roads and, therefore, perform very poorly on hills. If your car rolls freely when pushed as compared with other cars, the trouble must be in the gear ratio or the engine. If in the engine it may be due to a late spark, poor carburetor adjustment, loss of compression through the valve caps or around the piston, too great a clearance between the valve stems and guides, incorrect timing of valves, insufficient lubrication, too much cooling or a hundred other different things. It is true that considerable power is lost in transmission from the engine to the rear wheels. Each bearing absorbs a small percentage. Wherever a gear is employed, power is lost and the universal joints take their share. The power lost in universal joints is tremendous if the shafts are driven at a very great angle. Proper lubrication will minimize friction but will not entirely overcome these losses. A counterbalanced crank shaft reduces friction in the bearings and in that way causes less loss of power. In the ordinary crank shaft, the crank pins, part of the crank arm and the large end of the connecting rod cause considerable strain on the main bearings of the crank shaft when revolving at high speed, because of centrifugal force. In counterbalancing, weights are placed on the opposite side of the crank shaft so as to give a pull of equal force to that exerted by the crank pin and connecting rod bearing, in the opposite direction, thus causing no strain on the main bearings and reducing friction. Sometimes these counterweights are made part of the crank shaft and in other instances they are bolted on. The Prest-O-Lite system, with a magneto for ignition, probably could be installed at less expense, but a dynamo and storage battery might be found more convenient.

2160 Vacuum Feed Trouble.

From R. W. Smith, Idaho.—Kindly advise me in some early issue how I can overcome a difficulty with the vacum feed on a six cylinder car. When the car stops for some hours the gasoline drains from the vacuum feed back into the tank in the rear of the car. What causes it and how can it be remedied? I find it impossible to start the car until the vacuum tank is again filled.

Reply.—It is not possible for the gasoline to run back from the vacuum tank to the main tank with any vacuum system with which we are familiar. It is more likely that the line from the tank to the carburetor or the carburetor float valve leaks, allowing the gasoline to escape. If you have a vacuum system in which it is possible for the gasoline to feed back as you describe, it must be due to syphon action, and this trouble can be overcome by having the feed pipe lead into the top of the vacuum tank and not project down into the tank. The gasoline in the vacuum tank cannot drain out any lower than the lowest point at which this pipe enters the tank or projects into it. The only other way to remedy this difficulty is to install a light check valve in the gasoline feed line. If the vent in the main tank is clogged, there may be sufficient vacuum formed to draw the gasoline back, but this would also, no doubt, give trouble when running.

2161 Piston Ring Leak.

From F. E. Long, Idaho.—I have a Dodge car and in repairing it this Spring, I put one McQuay-Norris leak-proof ring on the top of each piston. Since I have put these rings on I have trouble with burning too much oil. I took the cylinder heads off and the chambers are full of oil. I use "Veed oil, medium." Please tell me what the trouble is in the next issue. Is it the oil or did I put the ring in

Digitized by Google

the wrong place? I used the old rings just as I took them out. Please tell me my trouble and how to remedy same.

Reply.—We do not believe the trouble is with the oil and the position of the rings is all right. The cylinders are probably worn slightly oval and piston rings do not readily adapt themselves to this shape. The old rings, no doubt, had worn oval with the cylinders and kept fairly tight. Although you put the old rings back in the same slots, you probably did not get them in the same position as regards the ovals or you sprung them out of shape in removing them and, therefore, they leak. We would suggest having a shallow groove turned in each piston directly under the lower ring, with holes drilled through the piston wall, so that the piston ring will scrape down the oil from the cylinder wall, and pass it through the piston back to the crank case.

2162 **Magneto Change.**

From G. K. Barnum, Oregon.—Please tell me through the columns of your magazine if a Bosch D. A. 2 magneto, such as is used on the Metz 2 cylinder runabout, can be changed for a 4-cylinder ignition and where would be the best place to get parts for such a change. I do not know the address of the Bosch Magneto Co. or I could get the information from them.

Reply.—The Bosch magneto cannot be altered to supply a four cylinder engine as none of the parts of any of the four cylinder magnetos will fit this type. The Sweet-Drain Auto Co. of Eugene, Oregon, are the nearest Bosch representative. They may be able to make a satisfactory exchange for you.

2163 **Trouble With a 1914 Buick.**

From Peter Rauch, Wisconsin.—This is my first attempt at asking you a question as a subscriber to your magazine. My car is a Buick, model B 25, 1914, second-hand, and is causing a lot of trouble. In the spring of 1916 it worked fine, except for a little adjustment of the Marvel carburetor, and everything was O. K., but in the fall trouble started. Now, this spring I had the valves ground in good, and tappet rods adjusted so they all clear the valve stem. The timer was adjusted for 1/10,000 and 1/15,000 inch play; carburetor adjusted, carbon cleaned out and the car worked like a top, but the next trip it would miss on one and two cylinders—the first and third. We put some other plugs in these cylinders and then adjusted the carburetor again, but no adjustment was correct, it seemed, until finally the engine backfired and off she went on all four. It worked fine for about 150 miles and then a knock became noticeable in the car when on a hard pull, and retarding the spark did not help any. I took the machine to a garageman, who was supposed to have had seven years experience. He said the knock was in the timing gear, as oil was put in instead of grease, which leaked out. He put in some grease which helped some. Then he ground all the valves, adjusted the tappet rods and as the lights were dim, he cleaned all the brushes on the generator. The car worked all right for about 50 miles. Now the starter is just about dead and the lights will just burn very faintly and she misses badly on 1 or 2 cylinders. Today I took the car to this garage and the repairman put in new plugs and adjusted the carburetor, but still it wouldn't work, and he took out all the valves again to be ground and he claims the trouble is too much oil. If this is true would there not be more carbon? My idea is there must be something wrong in the electrical parts, which he does not understand, as he admits that he has not fixed many "Buicks" yet. I hope you can give me a clear answer, telling me what you think is the matter with the car.

Reply.—If by the "timer" you refer to the interrupter points, 1/50th of an inch gap would probably give better results than 1/10,000. It would be well to clean these points carefully with emery cloth or a very fine, thin file. If the back fire was in the muffler it is probable that the muffler was partially clogged and the back fire cleaned it out. It would be worth while to take the muffler apart and finish the job. As this is a 1914 car, it is quite likely that the battery is about worn out and unless you know that it is less than two years old, we would suggest that you have it taken apart and examined. Too much oil will not necessarily give much carbon deposit because the oil might get on the spark plug and interfere with ignition so that the oil is not burned.

2164 **Misfires in One Cylinder.**

From W. Schrader, Illinois.—The car on which the following questions are based is a Stoddard-Dayton, model 11-B, 30 H. P. It fires regularly when running idle or when running at a high speed, but will misfire in one cylinder at a common road speed, say from 12 to 20 miles per hour. The valves have been ground, the carburetor and magneto cleaned and adjusted to various points without results. The magneto is a Bosch Du 4, and the carburetor is water jacketed. After a short run the grease works out around the valve caps and spark plugs. Do you think the piston rings leak? Can this cause it to misfire? Or do you think a hot air tube to the carburetor would help? When the engine misfires there is a knock somewhere, although the connecting rod bearings are all right. What can we do to stop the oil from flying out of the crank case at the rear bearing next to the fly wheel. We put in a new washer of brown wrapping paper and shellac, but it does not help.

Reply.—The oil working out around the valve caps and spark plugs may also get on the spark plug points and cause misfiring. On the other hand, misfiring from some other cause would leave the oil unburned and it would work out as described. If the trouble is due to oil, it may readily be detected by noting if all cylinders fire when clean spark plugs are put in. It seems more likely, however, that the misfiring comes from loss of compression, probably through a leak around the piston rings, or possibly at the points where the oil works out. The compression may be tested by turning the engine over with the starting crank and noticing if all cylinders have an equal resistance. It is usually necessary, with the present grade of gasoline, to supply heat to the carburetor to secure even running in cold weather. To prevent oil from working out of the rear main bearing, it will be first necessary to fit the bearing properly and then cut oil grooves in it, extending from the inner edge to within a quarter of an inch of the outer edge, so that the oil will be collected and drained back into the crank case.

Digitized by Google

2165 **Nitroglycerine.**

From R. B. Abronder, Texas.—I have been in quite an argument with a friend concerning the use of the so-called nitroglycerine in gasoline for automobile use. He contends that racing drivers, on the big speedways, do use a small quantity of nitroglycerine in their gas, as do also trick riders on motorcycle motordromes. I have never read of anything like this, and I say they don't use nitroglycerine, although they may dope up the gas in some way. Will you be good enough to give us light on this subject? Also please state at what speed a car has to move to stay on the Sheepshead Bay track.

Reply.—We have never heard of nitroglycerine being added to gasoline for use in an automobile. Racing drivers sometimes use small quantities of picric acid and ether, which they often term "dynamite" or "nitric." This may readily lead to the mistaken idea that nitroglycerine is used. It is not necessary for a car to move at all to stay on the inner edge of any part of the Shepshead Bay circuit. The banking at the turns is figured to permit a speed of about 120 miles per hour at the outer edge. It would be unsafe to drive a car on the outer edge at less than this speed.

2166 **That Ford Car Scraping Sound.**

From H. B. Smith, New York.—I think if R. A. Schell, Florida, will look at his pistons he will find one that rubs hard against the side wall, the top against the right side and the left against the bottom. The only remedy I know is over size piston. Please inform me if this is right.

Reply.—In our opinion over-size pistons would not be likely to overcome the trouble unless the cylinders are worn out of round, and then it would be necessary to have them rebored. Such a defect may have been due to some defect or wear of the connecting rod or its bearings, the connecting rod pin, the crank shaft or other part of the assembly.

2167 **Cannot Be Done.**

From William M. Watson, New Hampshire.—I have a Ford Model T car equipped wth a Bosch magneto. I wish to run electric lights from the original Ford magneto. How could this be wired with a New York headlight controller to have the dash and tail lights work together? What size and voltage bulbs should be used? Would these give a satisfactory light?

Reply.—The manufacturers of the New York Headlight Controller say that dash and tail lights cannot be used satisfactorily in connection with their device.

2168 **Battery Trouble.**

From G. H. Dueck, Canada.—I have a Willard six volt storage battery which was badly damaged by frost. It has stood about eight months in a discharged condition. Can it be brought to a condition so that it can be used again? One of the jars is cracked. Will it pay to buy a new jar and repair the battery? Can you tell me a firm where I can get a complete lead burning outfit?

Reply.—Whether or not this battery could be brought back to condition could be determined only by inspection, but in view of the fact that it has been discharged eight months and has a cracked jar, it would, no doubt, cost nearly as much to repair it as to purchase a new one. The following companies manufacture complete lead-burning outfits for battery work: Cox Brass Co., 1733 Broadway, New York; Oxweld Engineering Co., Newark, N. J.; Imperial Brass Manufacturing Co., 51 East 42nd St., New York.

2169 **An Unpleasant Noise.**

From A. W. Ingalls, Massachusetts.—I have a New Series, 1917 Chandler Chummy roadster, Maker's No. 36784. Have owned the car a month and bought it new. Ever since the first day I bought it, just as at present with mileage at 800 miles there has been a severe "back lash" and "slapping" noise under the car, apparently near the universal joint. The service stations in Lynn and Boston have taken the car down from differential to engine, made alterations, reassembled, and left the noise exactly as before. We have another Chandler car, also new, but minus this noise. The clutch is also apparently loose as it rattles badly when disengaged as the car comes to a stop. The "back lash" noise, however, is my main trouble, for it sounds continually at low speeds and especially over cobble stones, just as though the engine were skipping, which is not the case. I wanted to write for possible aid or information from any other Chandler owner. The Chandler Co. have not been able to explain the difficulty at this writing and it has certainly baffled all the local Chandler service stations.

Reply.—Very likely this noise is due to one of the rear wheels being loose on the axle shaft. This point might easily be overlooked because the sound would come, apparently, from the propeller shaft, some distance from the wheel. In this type of rear axle construction, the driving shaft is keyed to a flange which bolts to the wheel and forms part of the hub. To test for this trouble, put gear in first speed, remove hub cap, jack up one rear wheel, move it forcibly backward and forward, and observe if there is any play between the hub and the axle shaft. Repeat with the other rear wheel. Very close observation is often required to detect this play. Although the universal joints may be in good condition, they are likewise keyed on to the tapered ends of the propeller shaft, and these may be tested in the same manner, although the trouble is not so likely to be at these points. Another possible source of trouble is a loose fitting bolt through the torque rod, where it is fastened to the rear wheel. The clutch rattle sometimes is caused by worn or poorly fitting keys in the middle disc or high speed gear members that do not fit snugly. In either of these cases, the rattle would be most noticeable when coasting or applying the brake.

2170 **Loss of Power.**

From Edgar Weir, Virginia.—My car has been in use only about a year and yet it does not begin to run as well as when first put into commission. It has been run about 4,000 miles. It seems to have lost its power when going up hills and the engine knocks when going up a fair grade. What do you think is the trouble?

Reply.—In our opinion the engine should be cleaned of carbon, as it would be well to clean any car after it has covered about 5,000 miles, or even

Digitized by Google

less. It probably overheats. The spark plugs are in good condition or it would have developed preignition. Clean out the carbon well and see what the result will be.

2171 **Clutch Shifting Trouble.**

From G. M. Buckmaster, Oklahoma.—We have a Hupp "20" that when the shifting gear are in neutral and the engine cranked it runs very easy, but upon disengaging the clutch for the purpose of putting the car in motion, it seems to stall the engine; that is, the engine must be speeded up considerably before disengaging the clutch, otherwise it will stop. Seems to take as much power to drive the engine with the clutch pushed out as it does to propel the car when it is engaged. Can this be remedied, and how?

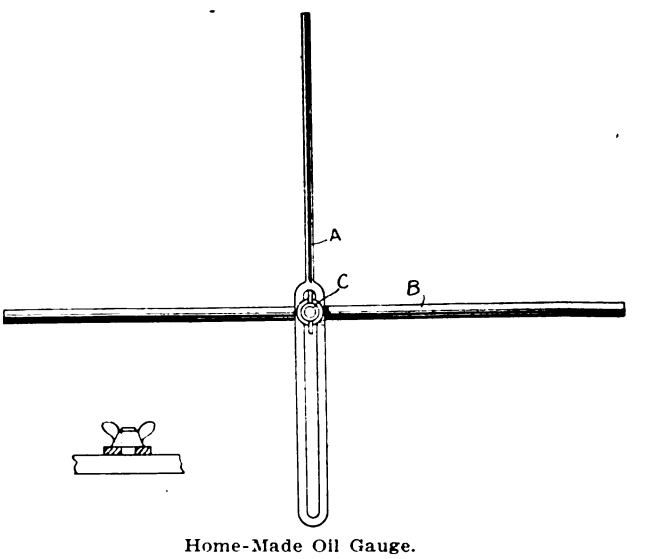
Reply.—This car has an inverted U-shaped bronze piece that fits in a slot in the clutch and is operated by the clutch pedal when the clutch is released. If this is not kept well lubricated, especially when it has become worn, pressure on the clutch pedal working against the resistance of the clutch spring causes a decided braking effect on the motor until the clutch has become fully released. There may easily be sufficient friction to stall the engine. This trouble increases as the clutch yoke wears. Keeping the part well lubricated with graphite grease should overcome the trouble if the yoke is not too badly worn. If worn, it may be turned around so that the opposite face bears or a new one should be installed.

Too Much Tinkering.

From G. E. Peterson, South Dakota.—If 90 per cent. of the drivers of automobiles would throw away their tools, they would have less trouble. Many of them use them merely to "show off" and yet they would not know a broken crank shaft if they saw it. I judge after seeing some people drive a car that the fools are not all dead yet, but the automobile is getting some of them. I was coming from Sioux City, Iowa, last fall on a trial. We were making about thirty miles an hour. An automobile driven by a woman with two children in the car was running alongside of the train and at about the same speed. The car was running wild and the woman was pinning on her hat. I should not like to tell you what I thought of that woman, but you can make a pretty good guess. I have been driving a car for several years and never had a serious accident, but have had some narrow escapes.

Cure for a Generator Trouble.

From E. C. McCall, New Jersey.—A rather curious occurrence on a 1916 Hupmobile, model N, came to my notice the other day. For some reason the Bijur generator was not charging the battery, which was gradually becoming run down. The dash ammeter showed no current even when the engine was raced. The repairman seemed to think the ammeter was burnt out. We hooked in a Weston ammeter and found no current. There is a small field fuse under a cover on top of the generator. This was found to be burnt out. After putting in a new fuse the generator charged in great style, the dash ammeter showing a strong current. But a new difficulty presented itself, when the ignition switch was thrown to "on," a short circuit was shown by the ammeter needle swinging violently over to "discharge." With the lighting switch "on" and ignition "off" no short circuit was shown so that apparently the "short" was somewhere in the ignition circuit.



This model N is equipped with Atwater-Kent open circuit ignition and the only time the current should flow is during the hammerlike blow of the breaker points. Examining the points carefully, we found the trouble. The points had pitted in such a way that they did not separate properly, thus causing current to flow and showing "discharge" on the ammeter. Whether this caused the fuse to blow on the generator, I don't know. Filing and adjusting the points cured the trouble.

That Dodge Car Noise.

From E. C. McCall, New Jersey.—In the April number E. E. Carpenter, No. 2125, reports a strange noise in his Dodge car. Your reply states it may be the fluttering of the auxiliary air valve of the carburetor. As all Dodge cars, which I have seen, come equipped with a Stewart carburetor which has no auxiliary air valve, this could hardly be the reason. I found that a mysterious rattle or squeak in my Dodge car was caused by the muffler plates becoming loose. To remedy this, tighten up the nuts on the long rods which run through the muffler lengthwise. If the nuts are up to the end of the threaded part of the rods so that they cannot be tightened, insert washers or slip a larger nut over the rod to act as a spacer or washer between the regular nut and the end of the muffler.

For Over-Lubrication.

From E. C. McCall, New Jersey.—I have a 1916 Dodge touring car, equipped with an Eisemann magneto. This car has gone over 8,600 miles. Of late I have had trouble with rapid carbonizing of

Home-Made Oil Gauge.

the engine, having had to clean out or burn out the carbon every four or five hundred miles. I was using Havoline medium oil right along, but tried Mobiloil A. I got even worse results with this, so I took the car to a repairman who makes a specialty of Dodge repair work. He took down the crank case to find out how far the splashers or the connecting rod caps were dipping into the oi

Digitized by Google

in the oil pan. This oil pan contains depressions, one under each rod, and there is a round hole at the upper end of each depression which acts as an overflow to keep the oil in the depression at a certain depth. By means of a simple home-made gauge (see sketch) he was able to measure how far the connecting rod caps dipped into the depressions. In my case he found that even the nuts on the connecting rod cap bolts were dipping into the oil at each revolution of the crank shaft, and throwing far too much oil up into the cylinders. He blamed the carbonizing on this. To remedy it he cut new holes in each depression below the regular holes, thus lowering the oil level in the depressions. He cut off the projections on the connecting rod caps and soldered on short pieces of copper tubing. These pieces were made slightly longer than the original projections so as to dip into the oil at the new low level.

I also had him install twelve American hammered piston rings. These are a one-piece ring, concentric. He also tightened up the main bearings and connecting rod bearings The job took one man 20 hours. Since then I've run the car 300 miles and am beginning to note a great improvement. The oil consumption is greatly cut down and the engine seems livelier.

The lower part A is slotted by means of screw C. A can be raised or lowered in relation to B. B is long enough to reach from one side of the oil pan to the other.

That Missing Front Cylinder.

From Leslie Nodle, Iowa.—In answer to Oscar Barnes, Wis., No. 2127, will say I had nearly the same trouble with a 1916 model Ford. I got it in December, 1916. I had to clean the plug after every run, so I put in a piston .0025 oversize (it was the first front cylinder) and it fit just fine. The car had run about 1,000 miles. It cost $1.35 complete with rings and pin. I hope this will help someone else. Since I have had no trouble at all.

Says Interlocks Pay.

From C. A. Pearson, Colorado.—In answer to 2082, will say from experience that it will not pay to use junk casings over good ones. I know it pays to use interlocks in casings that have been damaged through running with low pressure, bruised, punctured, etc. I have used them for years and have never worn one out yet.

The Stanley Steam Car.

The Stanley Motor Carriage Company of Massachusetts, with works at Newton, Mass., has been taken over by a new corporation of the same name, organized for the purpose, and incorporated under the laws of Delaware. Capitalization includes $2,500,000 of preferred stock and 100,000 shares of no par value common. None of this stock will be placed on the market for public sale. From the very first the Stanley business has been profitable and successful. In spite of the fact that advertising, publicity and aggressive merchandising methods were ignored, the output of the works at Newton increased gradually and Stanley cars have been produced in commercial quantities without intermission for almost twenty years. No effort has been made to get into quantity production in the modern sense, and the demand for the cars has always exceeded the supply.

The Stanley company has from the beginning held a firm conviction as to the superiority of steam power over the internal explosive engine, and the closest observation of the development of the latter during the last twenty years, nor even its very apparent popularity has not disturbed that conviction nor led them to make a change. The cars were well built and carefully made and record after record was smashed by stock cars both on the speedways and in the then popular hill climbs. Aside from the fact that the Stanley car burns kerosene and operates on steam, an interesting feature is the simplicity of operation and ease of control. One throttle lever under the steering wheel controls the car, and clutch, gears, gear shift and spark and gas controls are all eliminated.

This reorganization will have marked effect upon the general policy of the business. Immediate efforts will be made to increase the production. The factory capacity will be enlarged and further equipment installed, and it is announced that a strong modern merchandising effort will be put behind the product. Rumors that the Stanley company will bring out a cheap steam car are unfounded. The officers state that no changes in models or prices are under consideration.

THE COOLING FAN.

How to Make It Most Effective for Its Purpose.

From A. K. Schanze, before the Cleveland Section, S. A. E.—The cooling system of the internal combustion engine as now applied on a majority of pleasure cars, trucks and tractors normally divides itself into four main units. These are the water jacket around the motor, the circulating system, the radiator and the fan.

The order in which these have been named seems to be the order in their importance in the minds of most engineers, consciously or otherwise. It seems, at least, that this is about the historical order in which real scientific research and practical development took place on the cooling system today in use.

The author of this paper wishes to be recorded as being of the opinion that no order of relative importance can be assigned to these four subdivisions of the cooling system. They form a chain whose strength is only that of the weak link, and wherever there is a system in which one of the four parts falls below its proper standard of balance, there lies an imperfection in that system which should be remedied. Cooling systems give outward evidence of imperfections in two general ways, they overcool or they under-cool. Of the two the latter is far and away the more common.

Now, to take the discussion up in its parts, let us begin with the water jacket. Its functions, as we all realize, is to carry a quantity of water of such volume that it will take away from the cylinder walls only that heat that cannot be converted directly into mechanical energy, and the accumulation of which would be destructive to the material of which the cylinder is made. From such definition it would appear that, given the number of heat units generated, the mechanical work to be done, and the heat units in excess of the latter requirements, a water jacket would be a simple matter to

Digitized by Google

design. Perhaps it is, but its simplicity is a secret in possession of a comparatively limited number of engineers. It has been the writer's experience, during the various fan tests, that he has conducted on cars of many different makes, to come across three or four apparently ideal water jacket designs. In the main, water jackets leave some room for improvement.

The mere solution of the problem of what volume of water a jacket must contain does not produce the answer to the problem. The distribution of the water layers around the cylinder walls may take on an aspect of even greater importance than the volume. Since ignition takes places in the top of the cylinder, the top is longest exposed to fire and becomes hottest. Modern engineering practice has placed the deepest layer of cooling water over the top of the cylinder, which is as it should be. However, the foundry practice in some cases seems to have interposed stiffening ribs or small columns on top of the cylinder. These act as retarders to the circulation with the result that steam pockets seem to be formed. This shows itself in some engines whose water jacket volumes are adequate, in the sudden jump in temperature that takes place when the motor stops.

It has come to the author's notice on several occasions in tests that, when the motor was stopped, the temperature recorded by a thermometer placed in the filler cap mounted from 200 to 220 degrees Fahr. After losing two thermometers through having them blown out of an improvised bushing in a hole in the filler cap and seeing a jet of steam shoot 20 feet into the air from a radiator that a moment before had not been near the boiling point we became cautious and observant. Thermometers lashed in place showed that temperatures went to 220 degrees Fahr. Repeated experiments over the same ground could lead only to the conclusion that the whole mass of water was not being raised through that range of temperature in 40 or 50 seconds, but some little patch on top of the cylinder was being converted to steam and the filler neck was being used as a steam dome faster than it could act as a relief through the overflow.

The Water Jacket.

Wherever a design of water jacket allows of such a condition, every effort should be made to get rid of it. The condition is dangerous to the mechanical structure of the machine from an economic standpoint and is dangerous to people working around a car. The mechanical danger lies essentially in the radiator, where the large areas and thin structures are not designed to carry pressure. Steam above 212 degrees means pressure, and there is no doubt that many a radiator manufacturer has been called upon to replace a leaky radiator that was really not defective in its own right. The danger to human beings lies in the possibility of a clogged overflow pipe, and an unsuspecting person taking a look into the filler neck at the psychological moment. The writer was witness to one such case about one year ago where a man had his face severely scalded.

The water layer, then, over the top of the cylinder should not only be calculated upon a basis of its total volume, but should also be so arranged that the circulating system will handle all of it at a uniform rate, and so that, when the circulating system ceases to function, by virtue of the stopping of the engine, the layer will have a thickness such as to afford sufficient reserve to absorb the heat that remains in the cylinder after the last explosion, and no more heat is being added.

Tests conducted by various authorities on internal combustion engines indicate that high compression contributes the largest percentage of total efficiency of the gas engine. High compression is always attended by the danger of pre-ignition unless the cooling system can overcome the tendency. If the cylinder walls are cool, the gas upon entering the cylinder on the suction stroke does not immediately expand and fill the cylinder and prevent the full calculated quantity entering. It tends to keep its density in accordance with the carburetor regulation and then gives the engine more nearly the capacity of which a gas engine is capable.

In order to prevent the overheating tendency immediately following shutting down an engine, it would seem necessary then to give the water jacket such volume and distribution as to enable it to absorb the last head accumulations, independent of the circulating system.

Jacket design therefore should be such as to allow liberal distribution of water and freedom of circulation. Between the pump system and the gravity system of circulation there is, at present, somewhat of a race for supremacy. The pump system frequently over-circulates, or tends to, while the gravity system under-circulates. Both faults are conducive to trouble. It would appear, then, that it might be well to select a pump speed designed to do its circulating within the limits of the radiator frictional resistance and then always run the pump at that one speed regardless of motor speed. The gravity system of circulation has been used with varying success. At best its impulse is feeble, due to the lack of head. On this account it succumbs readily to any abnormal frictional resistances that may result from solid matter in the water.

Best results in gravity circulation as applied to the heating of dwellings and other buildings are obtained with the horizontal runs comparatively short as compared with the head. The principle is identical in the automobile. The head pipe must always remain well submerged. This latter feature cannot be accomplished without the use of a reserve storage tank attached to the top of the radiator.

The practical development of the system is still in its infancy and it is out of the question to say at this date anything but words of encouragement to users of the system.

Radiators offer about the largest variety of selection in the automobile industry. The radiator whose heat transferring qualities are such as to give a uniform rise of temperature to all air passing through it regardless of the velocity of the air is an ideal radiator and it is not beyond our reach. Some are in existence that so closely approach this condition as to be considered perfect to all practical intents and purposes.

Air Passages Should Be Free.

For efficiency, not only is it necessary to have the air passages free from solder obstructions, but it is just as important that they be of a size and shape that will give a good smooth run to the air. The more air that can be passed through a radiator the more will be its cooling power. As a practical suggestion to car builders the writer offers that every

Digitized by Google

purchaser be furnished a special card cautioning him to keep the exterior of the radiator clean as he possibly can. Much heating complaint would be avoided if radiators were kept clean. Tests go to prove that when a film of oil gathers enough road dust the radiator efficiency is reduced to about one-quarter normal.

The Fan.

Our last element in the discussion of the cooling system will be the fan. Altogether too little importance has been attached to this unit as is well illustrated by the fact that so few engineers know precisely how the relative values of different fans are determined. Researches made by some of the foremost radiator manufacturers have shown that cooling varies directly with the quantity of air passed through the radiator, when other conditions are reduced to the uniformity. It has, therefore, been the long time hope of many of the radiator manufacturers to see an improvement made in fans.

First and foremost, in the selection of a fan, should be considered the element of quality of air delivery. The ideal radiator, as has been stated, is the one that will give off its heat at such a rate that the air that passes out of it can absorb no further heat units. In combination with this radiator, the ideal fan is the one which will draw air through the radiator at such a high velocity that the air undergoes no measurable increase in temperature as it passes through. The fan is the only link in the chain that can be made of practically unlimited power without throwing the system out of balance. Incidentally, it may be remarked that fan manufacturers have the world still to conquer in that respect.

Fans of any one design increase their capacities in an approximate geometric progression with the increase in diameter. Best practice would therefore suggest the use of the largest diameter possible on any particular model of car. There are several distinct types of fans offered by the various manufacturers, classified for description as follows: rim fans, which are those whose periphery is bound by a circular rim; flat blade fans, which are usually of three or four flat blades built out from a central spider; curved blade fans, which are similar in construction to the flat blade fans except that the blades are curved somewhat after the manner of a garden trowel; and multiblade fans, which are of two or more arms, up to six, and in which each arm consists of two or more blades.

Flat blade fans are the most common in use at the present day. They are usually of the four blade type built up on a central spider. Their air delivering qualities are not good at low speeds, say, at a peripheral speed less than 5,000 feet per minute; hence they have to be run at very high speeds. High speed fans are noisy and consume a large amount of power.

The engineer, in making his selection of a fan, should take into serious consideration the amount of power necessary to handle maximum air velocities through the radiator. The author feels confident in making the statement that this phase of the question has been considered by very few engineers.

The summary of the whole situation is that, when the motor gets beyond a certain speed limit, such that the fan should begin to make from 4,000 r.p.m. up, the belt begins to slip, and once this condition has set in the fan becomes worse than useless for that particular set of conditions. A slipping belt does itself a lot of harm in addition to polishing the fan pulley so as to make the slip at normal speeds greater.

Wheel Puller and Arbor Press.

From E. A. Porter, Oregon.—I send a sketch of a home-made wheel puller that I use to pull off the hind wheels of my car, Fig. 1. A is a wood block

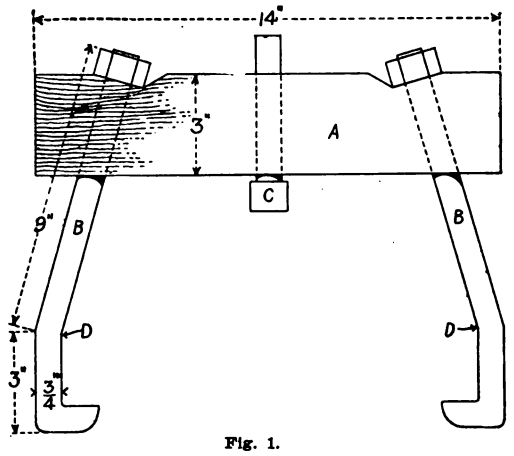


Fig. 1.

2½x3" by 14" long. B is made from ¾" round iron. C is a short piece of round iron to go against the end of the shaft. The hooks catch the edge of the brake drum. The bends in the draw arms as

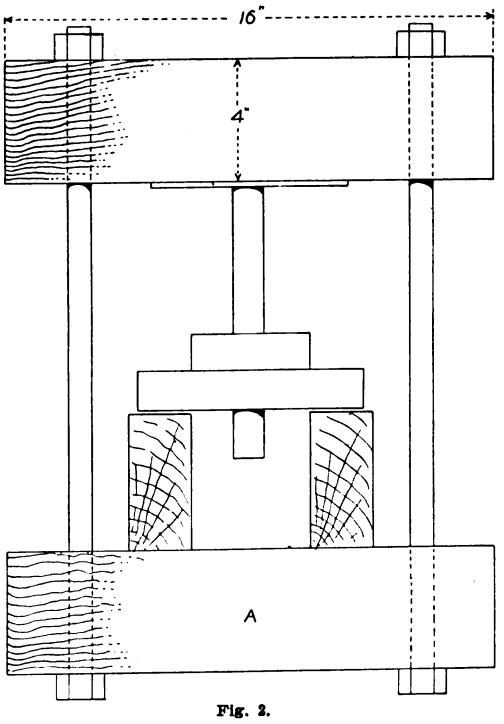

Fig. 2.

shown at D give them such a shape that they will not slip off. The block, A, is shown with a plunger through the center that can be struck with a hammer, but I use a plain oak block and strike on the

Digitized by Google

back of the block. I have used two oak blocks 4" square and 16", with two long ¾" bolts for an arbor press, Fig. 2. The lower block, A, may be bolted to the top of the work bench, or if the top of the bench is made of a heavy oak plank, the plank itself will take the place of the block, and a hole can be bored in it for the shaft to pass through.

THE GASOLINE SITUATION.

Director of the United States Bureau of Mines on the Subject.

V. H. Manning to the Business Paper Editors.—I am glad to be permitted to share in the patriotic endeavors of the business publishers and to bring before you, and through your public agencies, to the country, one of the, at least to my mind, serious problems confronting the United States at this time. I refer to the production and consumption of petroleum and gasoline in the United States.

To us who have looked into the insides of this problem, the situation is serious and it is my purpose here to give you a few of the essential facts and allow you to draw your own conclusions as to the remedies that ought to be applied. I shall transgress from this just for a moment to give you all the preliminary thought that, generally as a nation, when it comes to our heritage of splendid natural resources, we are wasteful, apathetic and forgetful. We waste our natural resources with shameful prodigality; we are apathetic of the future. It has been said that we waste our resources like a sailor spends his money on shore leave for the first time in a year, but from what I have seen of our national sin of waste I think we slander the sailor. I preface my remarks with the above because I wish to imprint the thought that any remedy that can be applied to the petroleum and gasoline situation will come through conservation, which does not mean tying up but a wiser use of what we have.

I suppose that you all are more interested in the motor fuel or gasoline situation than in the general petroleum situation, no matter how much one depends upon the other, and I am inclined here to give you a few of the outstanding statistics which will show you the crux of the problem. In the year 1916 there were two million seven hundred and fifty thousand automobiles, or an increase over the year 1910 of two million three hundred and fifty thousand. The increased number of automobiles in 1916 used a billion more gallons of gasoline or 28,000,000 barrels more than the automobiles in 1910.

This increased use of gasoline for the increased number of automobiles alone represented a little more than half of the total output of gasoline in the country in 1916 for all purposes, the total production being about 54,000,000 barrels. And when you realize that the number of automobiles is increasing with each day, you can grasp what a tremendous problem is this feature alone.

The total gasoline engine horsepower built and sold in the United States in 1913, according to the Federal Trade Commission, was eleven million two hundred thousand, and in 1915 the output had a little more than doubled, the figures being twenty-two million five hundred thousand. Just think of it, an increase in gasoline horsepower of 100 per cent. in two years' time.

These figures indicate the increased use of gasoline power more clearly than those which cover only the automobiles, as these include all types of gasoline driven machines which have been developed and increased in use in a way no less surprising than that of the automobile itself.

The apparently unsolvable puzzle about this is that while we have been increasing our production of gasoline, the production of automobiles has increased 200 per cent. above the increase in gasoline production. These are the facts that we must face. Where is it going to end?

Statistics indicate that of the gasoline produced in the United States, between 55 per cent. and 60 per cent. is used in the automobiles of the country, 20 per cent. to 25 per cent. is exported; and the balance is used in stationary engines, in motor boats, tractors and for various purposes of minor importance.

As the highways of the country are improved, the commercial trucks, consuming large quantities of motor fuel, are becoming important means of transportation in many localities. The fishing fleets of our entire coasts have installed gasoline power to replace their original sailing equipment. These fleets, with the many pleasure craft, operated mostly in the summer months, when the production of gasoline is most heavily taxed, use large quantities of this convenient liquid fuel. There seems no reason to believe that the call for gasoline will in any way be reduced; in fact, a much larger demand seems imminent.

As the production of gasoline depends upon our supply of petroleum, let us look to the source and see what we find. Petroleum and its products have become essential to our very existence. Gasoline is a very important product, but there are many others. The operation of hydroelectric generators, of railway and trolley cars, of the machinery of the factories, of internal combustion engines, of our battleships and our merchant ships, in fact, of all machinery is made possible by the use of lubricating oils, and these come from petroleum. Petroleum lubricates the machinery of the nation from the handicraft of the watchmaker to the dreadnaught of the navy.

The industry has progressed since its beginning a little over half a century ago, when it was possible to store the entire production in tin cans and wooden barrels, to the present, when the annual quantity produced requires great steel, concrete and earthen reservoirs for its storage, great pipe lines for its transportation and fleets of specially constructed vessels for its exportation.

In discussing briefly the supply and demand for petroleum in this country for the last few years permit me to say that the stored reserve of petroleum is the most stabilizing influence in the industry. I wish also to bring out the fact that during the last few months our increased consumption has made it necessary to draw oil from this storage which has convinced many people that our present supply has reached a point where it may never again be sufficient to fill easily the demand placed upon it unless some radical steps are taken to conserve its use. One of these steps frequently mentioned, and one that is slowly dawning upon our consciousness is that the burning of crude petroleum under boilers for the generation of steam ought to be stopped. In this way large quantities of priceless by-product

Digitized by Google

are being consumed with about the same abandon as an arson fiend destroys valuable property. I understand, however, that some of the western railroads that have been guilty of this practice are beginning to change their oil-burning locomotives to coal locomotives. One of their reasons in the past for burning oil in this manner was that it was then cheaper than coal, but this reason is fast disappearing.

In the year 1916 the marketed production of crude petroleum was, according to the estimate of the United States Geological Survey, two hundred and ninety-five million barrels. The stocks held by various pipe line and transportation companies at the end of January, 1916, according to various trade journals, amounted to approximately one hundred and seventy million barrels; at the end of 1916 the stocks amounted to one hundred and fifty million barrels, which represents a decline of twenty million barrels, even in the face of our greatest annual marketed production of two hundred and ninety-five million barrels.

If consumption of crude petroleum exceeds production, the difference must be drawn from storage. The question that naturally presents itself here is what of the future? During 1915 the normal consumption of crude petroleum was 12 per cent. greater than in 1914; and last year our consumption exceeded the 1915 consumption by 13 per cent. Estimating that the normal peace consumption for this year will increase at the same rate, or 13 per cent., our consumption for 1917 will exceed that for 1916 by about forty million barrels. This does not take into consideration the increased demand for petroleum and its products due to the entrance of this country into the war. Although this increased demand because of the war is difficult to estimate, obviously the increased use for various war purposes will greatly enlarge our consumption above the rate which prevailed during times of peace. The production of crude petroleum in this country during last year is thought to have reached high-water mark, and it is very likely that the production for 1917 will be smaller than it was last year. If the normal and war demands for petroleum can be filled, the difference between the estimated production and consumption during this year will amount to probably as much as sixty million barrels, an amount which must be drawn out of storage. With only about one hundred and fifty million barrels of crude petroleum in storage at the first of this year, and with the prospects of it becoming necessary to draw from that reserve probably sixty million barrels to fill that demand, it becomes more apparent that some radical steps must be taken to meet the situation.

It may be that as the shortage becomes more apparent the demand may lessen, but the calculations as given show the present tendency of our supply and demand and make it of the most importance to meet the situation with as little confusion as possible in our industrial life and without in any way hampering the outcome of the war. We should not pass over the situation with an optimistic statement that when the time comes new fields will be discovered, as has happened in the past, or that new methods will be found whereby this threatened shortage will be overcome. We should undertake to anticipate this problem as best we can, for we certainly will encounter it in the not distant future.

While the present increase in the number of pleasure cars may not continue, it is plain that the use of gasoline for power in many commercial fields has not yet fully developed and as this use widens it will more than overcome any falling off in the rate of consumption of gasoline in the cars used for personal purposes, if such falling off should occur.

The fact we must face is that the production of petroleum is not increasing as rapidly as the production and consumption of the gasoline. The petroleum in time will reach its maximum production and start to decline. What we are doing now is looking to more efficient methods of production from the oil sands, the production of more gasoline by the so-called cracking process, the extraction of vapors from natural gas, and the utilization of liquid fuels from other than petroleum bases.

More efficient methods of production are now being developed, such as the Smith-Dunn process for forcing oil from the sand by the use of air or gas under pressure.

The cracking of petroleum last year furnished 7½ per cent. of the total gasoline production and can be and is being developed and installed rapidly in most of the larger fields of the United States. Its possibilities are enormous.

The treatment of natural gas by compression, refrigeration and absorption produced sixty million gallons of gasoline of such low boiling point that it was mixed with equal parts of naphtha to form one hundred and twenty million gallons of good motor fuel. The compression and refrigeration process of extracting gasoline from natural gas, when first used, treated only gases containing three gallons or more of condensable vapors, but at the present time the development of the process and the increased price of the product make gas carrying one gallon profitable. The extraction of gasoline from gases containing less than one gallon and as small a quantity as one pint per 1,000 cubic feet is now being profitably carried on by the absorption process, which is well adapted to treating lean gases in large volumes. Another source of petroleum which will undoubtedly be developed in time is the shales containing considerable quantities of oil, but which, at present prices of crude oil, cannot be extracted commercially.

Substitutes for gasoline, such as the products of the distillation of coal, are being used at present in Europe for motor fuels, and may in time be used for that purpose in this country, as many by-product coke ovens are now being constructed.

In the periods of readjustment and in the development of latent resources, I am hopeful that the Bureau of Mines will play an important part. At present, besides endeavoring to meet the problems of today, the bureau is looking ahead and preparing to aid in solving the problems of tomorrow by investigating the possibilities of increasing the present production.

Automotive Electric Matters.

The first annual meeting of the Automotive Electric Association was held at the Homestead Hotel, Hot Springs, Va., May 17, 18 and 19. The attendance approximated forty from the following companies: Dayton Engineering Laboratories Co., Day-

Digitized by Google

ton, O.; Dyneto Electric Corporation, Syracuse, N. Y.; Electric Auto Lite Company, Toledo, O.; The Leece-Neville Company, Cleveland, O.; North East Electric Company, Rochester, N. Y.; Remy Electric Company, Anderson, Ind.; The Robbins & Myers Company, Springfield, O.; Splitdorf Electric Company, Newark, N. J.; U. S. Light & Heat Company, Niagara Falls, N. Y.; Wagner Electric & Manufacturing Co., St. Louis, Mo.; Westinghouse Electric & Manufacturing Co., Pittsburgh, Pa.

The objects of this association are to discuss subjects of interest and value to the industry in which its members are engaged, to advance and improve the industry by standardizing equipment and to standardize its application in co-operation with the Society of Automobile Engineers and the automobile manufacturers.

HUNTING TROUBLE.

Always Easy to Find Except in Case of the Automobile.

Ordinarily the fellow who starts to hunt trouble finds it quicker than he expected, but not so with the automobilist; when he starts to hunt trouble—in the car—it seems to be a very demon for eluding the searcher. Trouble will hide in a tiny piece of carbon lodged under a valve, or between spark plug points, in a wire that has jarred loose, in an interrupter point, a piston ring, a gas pipe—oh, in the most secret and insignificant place—in size—and just defy one to ferret it out. One learns that the insignificant things are really the most important at times.

Yet most of the troubles incident to the operation of a motor car may be located very quickly, if one will but go after them in a systematic way, and not wander aimlessly about the engine and other parts. The hardest thing a driver has to do when the engine stops or acts up is to divest himself of the idea that he knows just what the trouble is. He is sure he can fix it in a minute and he putters around a long time before he makes up his mind that it is something else, and it takes a lot of time to prove that to some persons.

"The best way to go about it," said H. C. Brokaw, principal of the Automobile School of the West Side Y. M. C. A., 318 West Fifty-seventh street, New York, "is to start without preconceived ideas as to what the trouble may be, and follow a system, which is really a process of elimination. To start a gasoline engine, three things are necessary—gasoline, compression and a spark at the right time. To keep it running it is necessary to have also water for cooling (unless an air-cooled engine) and oil for lubrication.

"If the engine stops on the road and pressing the starter pedal fails to start it, the first thing to do is to get the crank out of the tool kit and crank over the engine. If, with the gears in neutral, the engine cranks over hard, it indicates a lack of lubricating oil, or a lack of water, which has allowed the engine to reach a temperature where the lubricant fails to perform its work. If the engine turns over fairly easy it is not necessary to look for oil or water trouble.

"The next test is for compression. If the driver is not experienced and is unable to tell simply by the resistance to the starting crank if each cylinder has compression, he should open all petcocks except on one cylinder and turn the crank two revolutions, noting if there is a resistance for one-quarter of a revolution in the two revolutions. Compression occurs only on one stroke of the piston in the four stroke cycle. Each cylinder should be tested in a similar manner, opening all petcocks except on the cylinder being tested; see if the compression is practically equal in all cylinders.

"If one cylinder has very weak or no compression, the trouble will be found usually in the exhaust valve. First examine the push rod to see if there is clearance between it and the valve when the valve is supposed to be closed; if there is, the valve must be lifted out and the valve and seat inspected for carbon. Sometimes a piece of carbon will lodge on the valve seat, and, due to the hammering of the valve, will become fastened to valve or seat. For temporary repair generally it can be scraped off with a knife and the valve be ground in upon reaching the garage.

"If the trouble is not in the exhaust valve, it might be in the inlet valve. In some types of engines, the valve head may break off and get into the cylinder and when the piston comes up punch a hole in the piston head. A petcock may be loose so that it will jar open sufficiently to affect the compression and so cause the cylinder to miss fire. These troubles usually are confined to one cylinder and not to the whole engine.

"The gasoline is the next to be inspected. Is there gasoline in the bowl of the carburetor? This may be determined by inspection, opening drain cock, or "tickling"—flooding. If not, examine gasoline tank and see if there is a supply; then see if the shutoff valve in the line leading to the carburetor is open; if so, drain the bowl of the carburetor to get rid of possible water and dirt. To check the possible clogging of gasoline pipe or carburetor screen, notice if the bowl fills up again in a reasonable time.

"Do not adjust the carburetor. If the engine has been running it is practically certain that the carburetor has not become out of adjustment. Inspect the intake pipe, or manifold, to see if it has been loosened by vibration. If the engine still refuses to run, put about a tablespoonful of gasoline in each cylinder and crank over the engine. If this runs the engine for a few revolutions it indicates that the trouble is in the gasoline system and leaves but the spray nozzle, which may have dirt lodged in it, or the auxiliary air valve, which may be stuck, as remaining causes.

"Next inspect the ignition system. The first thing to do is to loosen one of the wires from a spark plug and lay or hold it so the bare end will be ⅛ inch from the base of the plug and have some one crank the engine by hand or with the starter. If a spark does not occur, go first to the interrupter points and short circuit the fixed point with a screwdriver or other metal tool and see if there is a spark. Examine the points for dirt and see if they come together and open properly. Then examine the condition of the battery, testing it. Examine the connectors on the battery, which sometimes jar loose; examine the wires leading to the interrupter and switch; see if they are loose, or broken, or short-circuited. This need not be done if the spark shows at the interrupter.

"Examine the distributor for moisture or dirt and

Digitized by Google

see if the wires have become loose. If a magneto only is used, it is a simple matter to see if the interrupter points are making and breaking properly and if the distributor is clean and dry. If these appear to be all right the trouble is doubtless in the armature winding or the condenser and cannot be repaired upon the road.

"The wires to the plugs may be burned or short-circuited. If, with an apparently good spark, we have compression and there is a mixture passing into the cylinders, the trouble may be in the spark plug. To test a spark plug it is necessary to remove it. Widen the gap to 1/8 inch and lay the plug with wire attached upon the cylinder; crank the engine and see if a spark jumps the gap. Widening the gap is necessary, because the spark will not jump so far under pressure as in the open air. If it does not jump the plug may have a broken insulator, or need cleaning. An extra set of plugs should be carried to replace those which become dirty; cleaning should be done in the garage. If uncertain about condition of plug, exchange it with one in another cylinder that is working properly.

"This covers most of the usual troubles experienced on the road. There are, of course, a great many other possibilities, but if these tests, carefully made, do not disclose the cause of the trouble, the novice would better send for a garage man. If one or two cylinders miss fire, the trouble is most likely to be caused through lack of compression or short circuited spark plug. If the engine refuses to run the trouble is most likely to be due to lack of gasoline, or failure of battery or magneto.

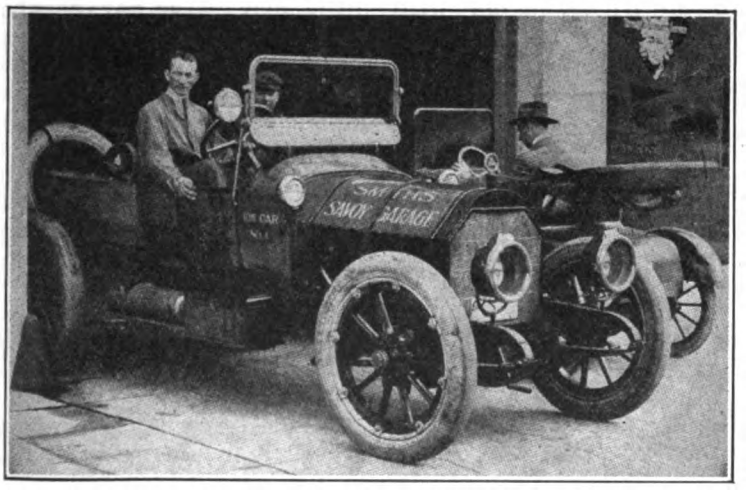
"The general rule given herewith should be cut out and pasted under the hood, or carried in an envelope in the tool box for ready reference. It may save much time and trouble when far from a garage. Carefully followed it should locate almost any trouble likely to be experienced, and it is the locating, not the fixing, which takes time."

General Trouble Rule.

Remove nothing except as directed in the test rules. Remember, the following conditions are absolutely essential to make the engine run:

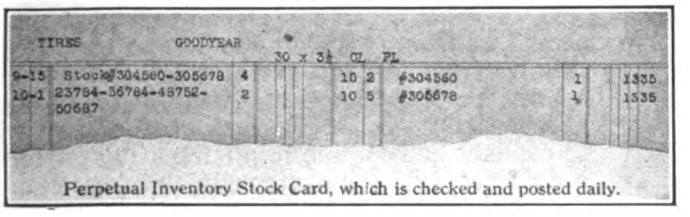
Gasoline—Is tank full? Are pipes clean? Is carburetor clean? If carburetor needs adjusting, do it, otherwise leave it alone. Does manifold leak?

Compression—To test—Open all petcocks except the one on cylinder to be tested; crank engine, noticing how strong the compression is in each cylinder.



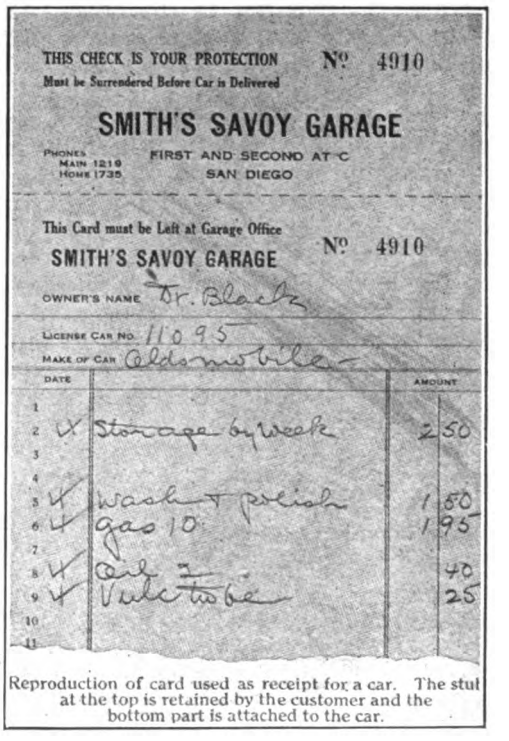
Ignition—A—Test for a spark by taking the wire off any plug; hold wire about 1/8 of an inch from plug; crank engine with switch on. Spark should jump to plug. B—Are the batteries run down? Does the vibrator (if any) buzz? Is timer clean? Do timer points make good contact? C—Are any wires loose, burnt, wet, broken or short circuited? Are spark plugs clean and are points 1/50 of an inch apart? D—Does magneto armature revolve? Is safety spark gap clean? Are interrupter points clean and adjusted right? Do all brushes make good contact? Is distributor clean? Is distributor rotor loose, broken, or making poor contact? E—Check magneto wires as per "C."

Loose wires and terminals and neglected batteries, also dirty gasoline, cause much trouble.



To keep a gas engine running. cooling and lubrication are needed.

Systematic Service Smith.



In San Diego, California, is a garageman named Smith. Motorists know him as "Service" Smith, which gives a pretty good line on him. No matter what a customer wants or when he wants it, Smith tries his best to deliver the merchandise. He has a key to each of the two leading automobile supply houses in San Diego, so that he can obtain a desired repair part at any time—nights, Sundays or holidays. He also has a key to the condition of his business, in the shape of a good set of books. You

Service Smith on Duty.

Perpetual Inventory Stock Card, which is checked and posted daily.

Reproduction of card used as receipt for a car. The stub at the top is retained by the customer and the bottom part is attached to the car.

Digitized by Google

could rout Howard B. Smith out of bed at two o'clock any morning and he could then and there tell you his assets and liabilities down to the last penny.

Smith's books prove to him conclusively that service pays. They also give him some information that is valuable in directing the business so that it will pay the highest profit. Every gallon of oil or gas that goes into his big service car (the only one in San Diego or Los Angeles that is always on call) and every expense connected with it is known absolutely. He knows that it pays mighty well to maintain this good service, or it would not be continued.

Smith is just as systematic about every other angle of his business. He takes absolutely no chances. Every time money goes into the cash drawer, a memorandum is made on the cash register tape as to what that money represents. Every morning these slips are totaled on an adding machine as to gas, oil, grease, storage, sundries, vulcanizing, washing, floor repairs, distillate, towing, tires, tubes, etc., and the various totals are posted to a daily sales record.

Customers' accounts are kept in a card index ledger, so that a floor salesman may refer to it when a question of credit is raised. The bookkeeper checks each account very carefully before sending out a monthly statement, for Smith realizes that mistakes would cost him either money or customers. Every day his bookkeeper posts the tire and sundry sales to an inventory card, and when goods of this same classification are received, they are posted to the proper card. The man in charge of the stock keeps a carbon stock book in which he records all goods received, and the carbon copy goes to the bookkeeper for posting to the office records. This perpetual inventory is checked by an inventory about every sixty days, by the aid of adding machines.

Realizing that quick sales mean bigger profit, Smith keeps a close watch of these inventory cards, and by so doing he knows which advertised lines are the best sellers. Just as he checks up his stock to prevent losses and pick winners, he checks up his invoices, ledger accounts, his bank balance and everything else into which human inaccuracy may enter. He wouldn't guess at his percentage of expense any more than he would guess at the quantity of gasoline he puts into a customer's car tank—everything is recorded. There's good profit in conducting a garage, provided it is managed according to modern business methods.

Visit the National Parks.

Secretary of the Interior Lane has announced that the National Park Service, recently provided for by Congress, has been organized, and Stephen T. Mather, of Chicago, appointed director of the service. Automobile maps of Glacier and Yellowstone National Parks have been issued by the National Park Service. These maps show the location of the hotels, camps, garages, and principal points of interest to the motorist. They contain also a small map showing the principal automobile roads tributary to and connecting the Glacier, Yellowstone and Rocky Mountain National Parks. Any motorist intending to visit the parks may obtain the maps free of charge from the National Park Service, Washington, D. C.

FIRE PROTECTION.

Vigilance and a Little Common Sense Are Far Better Than Loss.

From Murray Fahnestock, Pennsylvania.—A car is such a valuable possession that it is well worth while to use a little care to protect it against fire. Having the car insured is an excellent policy, as it not only protects the owner from loss due to fire, but relieves him of worry. However, insuring the car does not alter the fact that a burning car is apt to cause damage and loss to adjacent property. The owner of even a fully insured car, in fairness to his fellow motorists and the insurance companies, should take all reasonable precautions to protect his car against fire.

If an approved type of fire extinguisher is carried in the car, many insurance companies will allow a reduction in the premium paid for insurance which will soon pay for the extinguisher, not to mention the greater personal safety which the fire extinguisher affords. While it is true that gasoline is not nearly as volatile now as it was several years ago, it is also true that if it will burn in the motor, it will also burn outside of the motor, and it can be ignited by a very small spark. If the power plant is kept clean and in good running order, the chances of fire are but slight.

Many automobile fires result from the ignition of carelessly spilled gasoline, from back-fires through the carburetor, or from leaking gasoline tanks. The vibration of the car, as it passes over rough roads, subjects the gasoline supply system to severe strains, and a regular inspection is advisable. The gasoline may drip on the floor of the garage, and the vapor may be just ready to ignite, when some one enters and strikes a match or starts the motor.

If there are any oil lamps on the car, these should be, of course, extinguished while the tank is being filled. The gasoline vapors, forced out of the tank, when it is being filled, will sometimes drift for a surprising distance from the tank. If a fire should occur while the tank is being filled, the first thing to do is to cover the opening in the tank with any convenient object. If the regular filling cap is screwed on, the heated gasoline may exert sufficient pressure to burst the tank, and scatter the flames in all directions.

A careful driver will not attempt to start the motor, when a pool of gasoline has collected under the carburetor. Either the car should be moved away from the gasoline, or the gasoline should be given an opportunity to evaporate before attempting to start the motor.

If there is a pan under the carburetor, this pan should be fitted with an opening to permit gasoline leaking from the carburetor to escape. If dirt and oil are allowed to collect around the motor, they greatly increase the fire hazard, for they will tend to conduct flames, due to a back-firing carburetor or a defective ignition system, to the very combustible materials in the body of the car.

To keep the carburetor from flooding, clean gasoline should be used, as a leaky carburetor is most often due to a bit of dirt lodging between the float needle and its seating, thus keeping the valve open. Even when starting, excessive flooding of the carburetor should be avoided. If the ignition system is kept in good order, there is not much danger of a

Digitized by Google

spark occurring outside of the wiring and setting fire to any stray gasoline which may be present.

No "Hysterical Economy."

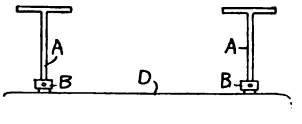
From the Curtis Pneumatic Machinery Company, St. Louis, Mo.—There is a tendency in some parts of the country to be over-cautious on account of the war conditions—"hysterical economy," some people call it. Your business has to exist during the war just the same as it does any other time. So, we may as well sit down calmly and face the true facts. What you want to know is whether your customers are going to stop buying abruptly, or gradually slacken, or what. As long as the people have more money than they ever had before, they are not going to stop buying, or limit their buying. The money of the world is in the United States today, in the hands of the people, and when they have money they are going to buy. Of course, prices are going to be higher, but at the same time wages are higher. With more money, the scale of living is better. More people are prospective customers today, especially in the automobile business, than ever before in the history of the trade.

There does not seem to be a chance at all for prices to come down before the end of the war; even after the war is over the readjusted scale of prices will be decidedly higher than were normal prices before the war. During the war labor will be scarcer. Wages will be higher. The scale of wages will not be reduced until we run into hard times again, and even then we have doubt as to wages ever equaling the lower wages prior to the war.

Every farsighted business man should, therefore, look ahead and protect himself. Don't stop buying now, because prices may go higher yet, and very likely will. Don't retrench, but adjust your business for what is only a readjustment of conditions. Business in the immediate future is not going to get worse. It is going to get better.

New Dearborn Truck Unit.

The Dearborn Truck Co., 2017 S. Michigan Ave., Chicago, is showing two new truck units, which have just been added to its line. These are a two-ton Dearborn unit adaptable for use with any standard chassis, and a new one-ton unit, which is also universal in its application. The Dearborn Truck Co. is a local company, the factory being located at the West Side, at 1250 S. Campbell Ave., Chicago.



Both of these new units are characterized by the same sturdy mechanical construction that has always characterized the original Dearborn truck units, which were designed for the Ford car exclusively. Ample provision has been made in their construction for overloading, the margin of safety being a liberal one—50 per cent. above rated capacity. Unusual interest in these new units is being shown by Dearborn dealers in all parts of the country and a large number of orders has been booked for immediate delivery, on both types.

Anticipating a rush of orders for these new types of Dearborn Units, the Dearborn Truck Co. withheld its announcement of them to its dealers until both were ready for distribution in quantities. The volume of orders, which is daily increasing, indicate that the Dearborn factory would have been swamped had this information been in the hands of their dealers previous to the introduction of these two new models. It is expected that the introduction of these two new units will have a definite bearing on the solution of the used car problem. Being practical for use with larger power plants than the one-ton Dearborn units, which have given such splendid service with the Ford car, these two-ton units can be attached successfully to power plants of 40 to 50 horse power; cars such as the Pierce-Arrow, Packard, Peerless, Lozier, Locomobile, Oldsmobile and the larger models of the Hudson and Chalmers, and other cars in this class. Owing to the relatively high cost of upkeep on these larger cars, dealers have been built along mechanical lines that will state at prices that are really far less than their actual worth. All of these larger, high priced cars have been built along mechanical lines, that will enable them to give good service for the next five or ten years to come; and a more ideal combination for an inexpensive two-ton truck is hard to imagine than the Dearborn and one of these cars. Other cars that will give good service with the new units are the Overland, Maxwell, Buick, Dodge, Studebaker, Hupmobile, Chandler, Apperson—in fact, any chassis is adaptable.

The new two-ton Dearborn units are built with heavier frame, wheels and general all round heavier and stronger construction to meet every condition of hard service. Their specifications speak truck quality. Five inch channel frame dead axle 2½x2 inches drop forged and heat treated; heavy 3-inch springs, 48 inches long and 9 leaves, with bronze bushings in eyes; additional relief spring over rear axle; heavy truck wheels 34x5 inches, guaranteed hickory spokes and felloes, has 12 2½-inch spokes. Solid rubber tires, 34x5 inches; 1¼-inch pitch Baldwin roller chains and Baldwin steel sprockets. Loading space for 10-foot body.

To Lift a Cylinder Head.

First insert a T wrench, A, from which the socket has been removed, into the shell of a spark plug, B,

riveting same at C. Make two of these. Place one in each end of the cylinder head, D. The head can then be removed evenly and easily without damaging the gaskets.

Silencing the Ford.

The quest for silence should begin before the car is purchased, by a careful study of the instruction book. The new car should be run most carefully, for then the car is new to the driver and the driver is new to the car. The Ford should have about five quarts of oil in the crank case, until the cinders and grit, which have probably entered the bearings during the car's journey from the factory, have been washed out. If the car is run at a moderate speed for the first week or so, the bearings will have a chance to bed themselves down to smooth, close-fitting surfaces which will tend to eliminate noise and wear for a long time. The idea should be to break in the car easily, and not to break it up.

Noise is often the danger signal of wear and possible breakage, for noise is usually due to the rubbing of unlubricated surfaces or to the hammering of

Digitized by Google

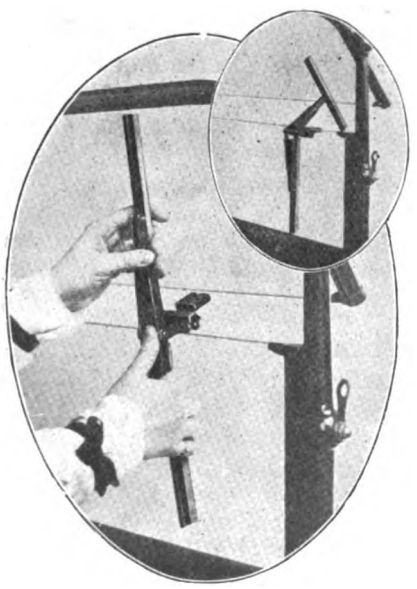
loose parts. If the spring shackle bolts are noisy from lack of lubrication, it is certain they will wear rapidly. If they rattle because they are loose, the hammering action is apt to cause rapid wear and eventual breakage.

If small parts are worn, it is often better to replace them and thus to keep the car up to a high standard of efficiency, than to attempt makeshift repairs. If a bushing is worn, it is often advisable to replace the pin also, for a worn pin will soon wear a new bushing to a loose fit and will thus curtail the value of the repair.

Some noises and squeaks are rather difficult to locate, but they can generally be found by a process of elimination. If certain sounds are heard when the motor is running and the car is at rest, it is reasonably certain that the trouble is in the motor. Another test is to disengage the clutch and stop the motor while the car is coasting down hill and thus locate chassis squeaks.

Jumping on the running boards, while the car is at rest, is a useful test for locating spring and body squeaks. If the mouthpiece of a megaphone is held near the ear, the large end of the megaphone can be used to locate the direction of the sound. By eliminating other noises, the megaphone makes the source of the noise easier to locate.

Flat surfaces in the mud guards are apt to vibrate and drum. This can often be cured by bending these flat surfaces slightly so that they are either convex or concave and are thus supported against vibration.



Watching Braking System.

It is imperative that drivers take particular pains with braking system of the car; because at this time of the year, when touring is at its height, nothing is more essential than a good set of brakes that are capable of holding the car on a steep grade. Some owners, to make certain that no trouble will result, have the brakes relined each season and make a careful inspection of them whenever a long run is to be made, in much the same manner as an engineer sees to it that the brakes of the train work properly. The linkage from the pedal or lever to the bands should be carefully gone over and all joints well lubricated.

NEW AND INTERESTING THINGS IN MOTORDOM

Clears the Windshield.

A protection for motorists which fills a pressing need comes in the form of : clearer for the windshield, and is known as the Universal Rain Rubber. The device clears both the top and bottom glass clean across and has as its unique feature a traveling section which slides in the slot. It attaches instantly—holds firm as a vise—but slides without effort.

Universal Rain Rubber.

Multiple rubber—two pieces of gum rubber—make the cleaner flexible with two cleaning surfaces on each arm. The rivets are topped with celluloid heads, which will not scratch the glass. A single stroke of the hand moves it from one side to the other. One of its most desirable features is the fact that it can be removed by simply opening the glass and lifting the rain rubber off. It is made in five different models designed to cover any known type of two-piece windshield. Manufactured by Tri-Continental Corporation, Buffalo, N. Y. Price $1.50.

Maxwell Sales.

Sales of the Maxwell Motor Co. during the first three months of 1917 were more than 58 per cent. larger than the corresponding period of the preceding year. The total for the quarter was 19,000, an increase of 6,968 over the first quarter of 1916. It is anticipated that there will be a surplus account of $600.000, after paying the usual dividends of $3,000.000 and a possible Government tax of between $500,000 and $600,000.

For Starting and Lighting.

The brushes used in the starting and lighting equipment of a car wear out and burn out from time to time and nothing can be done about it except to get new ones. The National Carbon Co., Cleveland, Ohio, make a pyramid brush for every car that is equipped with starting and lighting. The firm's specification sheet lists the brushes for practically every car made. A copy of this will be sent on request.

The Burrill Tire Tool.

Through a printer's error the address of the Burrill Tire Tool Company was not given in a notice on their tools which appeared in the May number of the Automobile Dealer and Repairer on page 94. It is Concord Junction, Mass. We have had several inquiries for the address of this company.

Make This Sign Pay Your Rent.

The Flexlume Sign is a money maker for the garage man or dealer. It is always on the job of inviting work and the best motorist cannot fail to see it. It gives a maximum of brilliant light and does it economically. It has a certain distinctiveness that is lacking in most other signs. It is not expensive and if necessary can be bought by the easy payment plan. Those interested should address the manufacturers, The Flexlume Sign Co., 1445-1451 Niagara Street, Buffalo, N. Y.

Ford Radiators and Hoods.

There is an unusual large call from Ford car owners and dealers throughout the country for a 1917 radiator and stream-line hood to be used on 1915-16 model Ford cars. The Superior Lamp Mfg. Co. of 136 West 52nd St., New York City, has brought out a similar reproduction of the 1917 Ford radiator in black enameled finish and a stream-line hood to go with it, as a complete

Handsome and Well Made.

outfit which lists at $35.00. This outfit can easily be applied to a 1915-16 Ford car, changing it into a 1917 appearance. This same company issues a booklet entitled "Bulletin No. 5" which has just come off the press, and contains various interesting items for Ford cars, such as demountable wheels, wind-shields, tool boxes, crown fenders, etc., etc. Bulletins can be had by mailing a request for them.

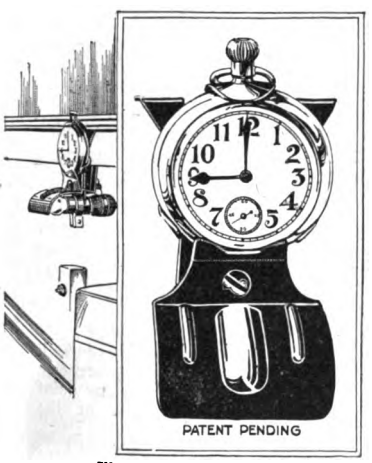
A New Automobilist's Plier.

A handy vest pocket plier (5½ inches long) has just been added to the extensive line of "Red Devil" Pliers. It is a very well finished nickel-plated tool and special features such as knurled handles and specially designed jaws make it serviceable for doing light work around automobile engines. The gripping jaw



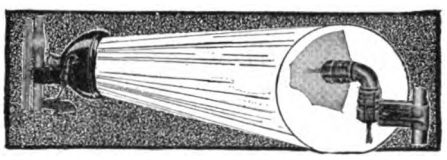
"Red Devil" No. 24.

is adapted for handling pipes, wires, square and hexagon nuts and irregular shaped objects. The jaw is provided with a slip-joint making it adjustable for gripping larger shaped objects. The manufacturers are Smith & Hemenway Co., Inc., 83 Coit Street, Irvington, N. J., manufacturers of the well-known line of "Red Devil" Tools.

Dash Light and Illuminated Clock.

This efficient dash light and clock fits in the cowl beneath the wind-shield; illuminates the entire dash; lights up the foot pedals, coil box, speedometer, etc. Will not shine in your eyes; almost unnoticeable. Securely attached by means of clamp on the angle iron beneath the wind-shield—no drilling. Easily at-

Illuminated Clock.

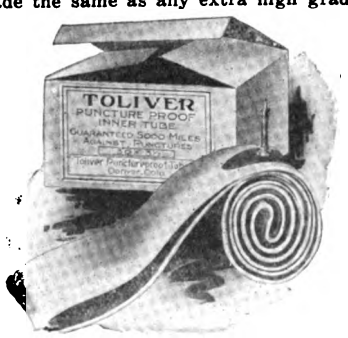


tached, but cannot be removed without screwdriver. Current for this light is supplied from the Ford magneto, therefore at no expense; can be turned on or off at will. Sold complete including wire and bulb ready for use. Made by Rose Manufacturing Co., Philadelphia.

A Tire Tester Attachment.

This is easily attached and will give any service station a permanent holder for its gauge. It is really a tire tester and tire inflater combined. Every garage with free air should be equipped with this Romort automatic air valve and tire tester. It is made by the Romort Manufacturing Co., Seattle, Wash., and Chicago, Ill.

Howe Spotlight.



"That the spotlight has come to stay is proved by the numbers sold"—said an official of the Howe Mfg. Co., of Chicago to a representative of this magazine. "The growth of this industry can be compared with the automobile industry itself—we all remember when automobiles came out—only a few people believed in them. They were looked upon as a plaything—as a rich man's luxury. No one ever dreamed that some day there'd be five millions in use. For a few years the sales of cars numbered by the tens, then by the hundreds. The motor car was still a very imperfect machine, but with the advent of dependability, a veritable craze for automobiles hit the American people. They bought blindly. Anything that had wheels on it—anything that would run—found ready sale. So it has been with the spotlight. But the car owners soon waked up to the fact that any light that would fasten onto their windshields wasn't a spotlight—just like they soon found out that anything that had four wheels and a gas motor wasn't an automobile. He knows the spotlight fills a real need, but he also knows the qualities a spotlight must have to meet the need. The 1917 buyer will demand a spotlight that is easy and quick to control and that will hold its position when directed. He will examine the switch and make sure it's easy to operate—look at the wiring with a critical eye and turn down the spotlight that gives a suspicion of ever coming to short circuits. This is the reason for the big sales of the Howe Spotlight."

The Howe Spotlight.

Tire Absolutely Puncture Proof.

Motorists who have had many a pleasure spin marred by puncture troubles will be interested in the Toliver Punctureproof Tube which is guaranteed 5,000 miles without a puncture. It is made the same as any extra high grade

tube and is inflated with air in the usual way, but the secret Toliver Process makes it punctureproof. It is claimed that many users get as high as 12,000 miles service without a puncture. The manufacturers, The Toliver Tube & Tire Co., Denver, Colo., will send complete details and prices on request.

Resignation.

Mr. V. W. Kliesrath, for many years chief engineer of the Bosch Magneto Company, has severed his connection with that company, at the close of a long and successful period as head of the technical department of this celebrated concern. From the very inception of automobile racing, as well as motor boat racing and aviation contests, Mr. Kliesrath has been a prominent figure, known to all interested in the racing circles, where he has always been in charge of a most efficient corps of technical experts at the service of manufacturers and interests of the various racing equipments. Mr. Kliesrath's plans for the future have not as yet been announced.

Counter Display Card.

The Twitchell Gauge Company of 1212 Michigan Avenue, Chicago, offers to dealers an attractive counter display card which holds a dozen Twitchell

You can sell a dozen from this Display Card faster than half a dozen packed away on your shelves.

Gauges, cut of which is shown herewith for reproduction. Wherever used, these sales helps have been found greatly effective.

The Petry Cut-Out.

Cut-outs for automobiles are something like the little girl with the curl—"When they are good they are very, very good and when they are bad they are horrid." The Petry cut-out is of the very, very good kind. It is positive. It is noise-proof when closed, light in weight, strong and easily attached. It has many other advantages because of its scientific design and fine construction. The prices for it are unusually low and it will pay dealers to secure the agency if possible. It would be well to write or wire at once. A handsome counter display is sent with an order for twelve assorted sizes. The manufacturers are N. A. Petry Company, Inc., 1313 Race Street, Philadelphia, Pa. There are distributors at four or five important points in the country, which makes securing the goods comparatively prompt and easy.

Keep Your

Johnson's Carbon Remover

Cures 80% of Engine Trouble

That knocking in your engine—the difficulty you have climbing hills—poor acceleration—lack of power—pre-ignition—noisy motor, are all caused by carbon.

Put New Life in Your Engine

with Johnson's Carbon Remover and it will run like it did the first 500 miles—quietly and full of "pep." No matter how choked up your motor may be, Johnson's Carbon Remover penetrates and softens the carbon. It then burns and powders and is blown out through the exhaust.

You Can Do It Yourself

Five minutes' time and no labor required. Simply lift the hood and pour an ounce of Johnson's Carbon Remover into each cylinder through the petcocks or spark plug openings. Go to bed—get up in the morning and drive a perfectly clean engine.

Use It Every 1000 Miles

If you will use Johnson's Carbon Remover at regular intervals, giving carbon no chance to accumulate, you will automatically eliminate most valve trouble and your engine will always be at its highest efficiency.

Pints $1.00

Johnson's Stop-Squeak Oil

Has the Remarkable Property of Seeping Rapidly Between the Spring Leaves

and to the furthermost wearing points and it there becomes a heavy-bodied lubricant.

The irksome task of jacking up a car, prying apart the spring leaves and lubricating them is forever done away with. You, yourself, can now keep your springs thoroughly lubricated at all times. All you need is Johnson's Stop-Squeak Oil.

Make Your Car Ride Easily

Johnson's Stop-Squeak Oil is a simple remedy for hard riding cars. Instead of bumping over the road, you fairly float along if your springs are lubricated so you have spring action. Johnson's Stop-Squeak Oil reduces the liability of spring breakage.

For Squeaks of All Kinds

Johnson's Stop-Squeak Oil will remove squeaks of all kinds—in springs, shackle bolts, body, fenders, top, etc. Just locate the squeak and touch it with Johnson's Stop-Squeak Oil.

New Energy for Spark Plugs.

The P. S. E. Spark Plug Energizers introduce a well-known electrical phenomenon, breaking a circuit and introducing air resistance. Thus the amperage is slightly decreased and the voltage much increased. A gap in an electric circuit forms an effective resistance, and resistance of any kind increases speed or voltage the same way as the resistance of the nozzle on a hose increases speed of water. And it is a well-known fact that increased speed causes increased heat. The metallic screen surrounding the spark creates a condenser

The Speco Energizer.

action, which so greatly increases the voltage that not only is the heat increased but the voltage stepped up to such an extent that the electric circuit will unfailingly seek the next gap regardless of obstructions. This means that not so much current is used, but the spark is hotter and will go through any amount of carbon, grease, oil, soot and will even fire a plug with broken porcelain. Not only are the dozen or more old, dead plugs you have accumulated restored to indefinite life, but it means insurance against spark plug trouble. On commercial motors, pleasure or physicians' cars, yachts, launches and stationary motor, it may save dangerous delays and disagreeable experiences in bad weather or on hurried trips. A hot spark means complete combustion, the last ounce of power from every drop of gasoline, the elimination of smoke and carbon and a smooth, powerfully running motor. P. S. E. Plug Energizers are retailed under this guarantee: "Try it ten days and if not absolutely satisfied—your money back." Price each $1.00. P. S. E. Manufacturing Company, 1777 Broadway, New York.

Eagle Macomber Motor Car.

Frank E. Barnes has resigned his position as superintendent of the King Motor Car Co. to assume the position as production manager of the Eagle Macomber Motor Car Co. of Sandusky, O. When leaving the King Co. he was presented with a valuable watch and chain by the department heads as a token of their appreciation. The Eagle Macomber Co. are making every effort to build the strongest possible organization as extensive production plans are being made for the coming year. The company has been working quietly until the car and the plant were ready for actual production. This has now been accomplished. The plant is completely organized. Materials are already on hand to begin production not later than July 1st. It is announced however that no cars will be available for the public for some time after this as orders are already on hand for a large number of cars. The Eagle car is fitted with the Macomber air cooled rotary motor for which advantages are claimed. A complete announcement and description of the car and motor will appear at an early date.

What's to be Done About Country Road Glare?

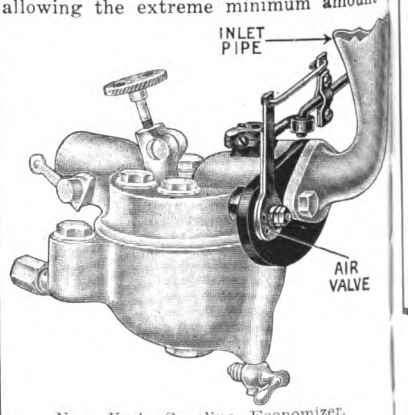
What is the solution of the "headlight glare menace"? Is it "dimming," "deflecting" or "diffusing"? Certainly the motorist cannot drive with any less light—what he really needs is more light. The question is how to get it without danger to the "other fellow." The number of lenses of different types recently brought out indicate an effort to change the quality of the light from the headlights. The widely different effects from different lenses would, however, seem to indicate that no definite idea has yet been universally adopted as a satisfactory solution. For instance, one type of lens seeks to remedy the menace simply by breaking up or diffusing the light rays. Another type does not change the rays but endeavors to correct the glare evil by deflecting the light so that the rays do not rise above a certain level. But there are still the two bright lights, the faces of which are fully visible. Perhaps a more satisfactory means for country driving and for passing other cars is the Windshield Searchlight. The spring controlled bracket, by which the movement of the best searchlights is controlled enables the driver to tilt his searchlight at an angle which throws the light only on the road and at the same time hides the full view of the face of the searchlight from the approaching motorists. With a good searchlight on the windshield, headlights can be switched off entirely and yet each driver has all the light he needs right where he needs it.

Some Truck Load

When a three-ton F. W. D. (four-wheel drive) truck hooked to a thirty-ton wagon will, with a heavy load, keep on its way through a big cinder covered field, sinking ten or twelve inches into the ground, it readily will be admitted that it is "some" truck. When this load is a total of twenty-two tons, which includes a sixteen-ton girder, seventy-one feet long, one is still more ready to concede that "some" truck does not do the truck justice. A Clintonville truck recently made the trip from the Wisconsin Bridge & Iron Works in North Milwaukee, Wis., to the Northwestern Bridge & Iron Works, at Twenty-ninth and Hopkins Streets. A stop was made for the noon hour, during which time the heavy truck and its load cracked the macadam on which it stood. The haul was made under the direction of George Roberts, local representative of the Clintonville F. W. D. Co.

Auto Suggestions.

This is the title of a house organ issued by the Northwestern Chemical Company, Marietta, O., and it is of about the right sort of size, the right kind of printing, and the right sort of editing, to make it readable and inviting. It requires one whole page to catalog the line of chemical productions this company manufactures. Better send for a copy and get information and amusement.



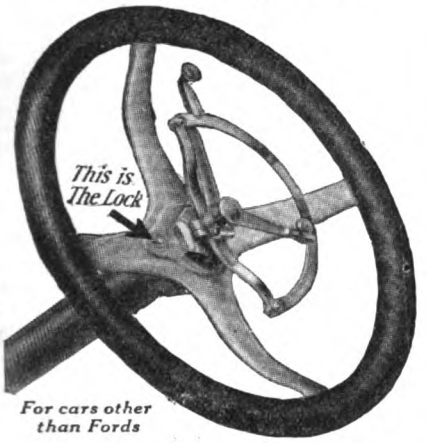
Vitality Supreme.

By BERNARD MACFADDEN, Physical Culture Publishing Company, New York.

There are a good many physical culture books on the market just now, and this is on the whole one of the best for the many who are enough interested in the subject to try to achieve health by exercise and diet, which is better than to try to do so by other self treatment. As is well known, the author has made a life-long study of physical culture and those who will faithfully follow his directions cannot fail to secure health, vitality and strength according as it was given them by inheritance. The book is readable, comprehensive and well illustrated. It contains 260 pages and is well bound. It gives instruction as to proper breathing, what and how to eat, blood purification, exercise for vitality building, bathing, breathing, sleep, cleansing the alimentary canal, etc. No one leading a sedentary life and fail to have improved health if he will carefully read it and then follow its instructions.

Costs Little, Saves Much Fuel.

The New York Coil Company, 338 Pearl St., New York, manufacture a gasoline saving device known as the New York Gasoline Economizer. Its manufacturers lay great stress on the fact that it is not to be regarded as a suction-operated air valve screwed in the inlet pipe but is attached to and becomes a part of the present Ford carburetor. It is installed without drilling or tapping between the inlet pipe and carburetor and is connected by a simple linkage with the throttle rod. As the throttle is opened air in mathemetically fixed proportions is admitted at a high velocity to the over-rich gasoline mixture, allowing the extreme minimum amount



New York Gasoline Economizer.

of fuel to be used. This concern further points out that practically every high grade present day carburetor has built into it a device for performing the same function, and claim that this attachment places the Ford carburetor in identically the same field as the most expensive carburetors used on high priced cars. The price is $2, and it is thoroughly guaranteed. Interesting literature will be mailed upon request.

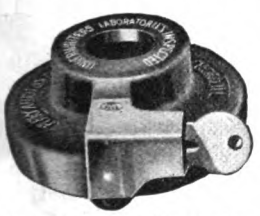
Are You a Standard Dealer?



A Thief-Proof Lock For Every Car

For cars other than Fords

The "Perry" fits every make of car. Can be installed by any mechanic in 15 minutes. Does not interfere with or change any of standard parts of steering gear. Absolutely safe to drive when unlocked. And no one can drive or tow a car when "Perry Locked."

For Fords—$5.00

Fastest selling Ford specialty the trade has ever seen. Greer Automobile Co. sold 95 of the first 100 inquiries. Lock replaces standard Ford cap on planetary housing below steering wheel. Liberal profit to you. Write today for prices.

AUTOMOBILE owners prefer to trade with standard dealers—dealers who sell nationally advertised standard accessories.

There are standard tires, standard lubricating oil, standard speedometers, etc., each the standard in its class.

The Perry Lock is the standard automobile lock. It reached this distinctive place because it is the simplest, the best, the most practical. It CAN'T get out of order.

50,000 "Perry" Locks are sold every month. It proves that it is the ready seller with greatest merit.

"PERRY"

The Only Lock That Thieves Won't Touch

Your profit, Mr. Dealer, lies in the article which sells the most readily—on which you can make the quickest turn-over of capital.

You make two profits on "Perry" Locks because you will sell two "Perry" Locks for every one you sell of any other kind.

You don't have to explain anything about the "Perry" Lock. You simply say "One turn of the key disconnects the steering wheel and the car can't be driven or towed away."

The "Perry" takes the place of other locks. You don't have to carry a large stock of all kinds. Show your prospective customer the "Perry" Lock and he will take it. He knows it is a standard article and standard articles are the safest to buy.

The demand for "Perry" Locks is increasing. Are you prepared to get your share of the profits from the sale of Perry Locks in your community?

Small stock—big demand—quick turnover—good profit—that's "Perry" Lock.

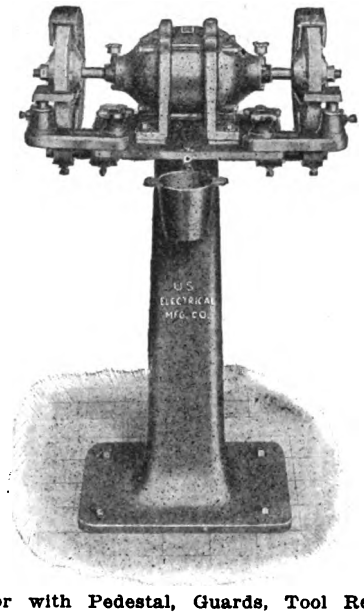
A New Bumper for Fords.

The demand for a rear end bumper on Ford cars has prompted the Gemco Manufacturing Company of Milwaukee to design one. Its popularity is increased by the fact that it is a neat job. It is light in weight and has a special carrier for tires, lamp and license bracket. This special carrier is not a permanent fixture, but may be added at any time. It can, however, only be used in connection with this special rear end bumper for Fords. When the Ford is fitted with a front end bumper and a rear end bumper, the wheel base is seemingly lengthened, thereby adding to the appearance. The attachment is made to the car's rear spring, therebv simplifying the work for the garage dealer. This new accessory is rapidly being introduced in the markets so that they are already on inspection at many garages. Favorable comments are freely being made by Ford car owners.

Remarkable Growth.

On and after June 1 the Apco line of specialties will be manufactured and marketed by the Apco Mfg. Company, Providence, R. I., which concern succeeds the Auto Parts Company. The new company is capitalized at $200,000, an increase of $170,000 over that of the former company. The plans call for an increase of factory space of over 50 per cent. This was necessary owing to the increasing demand. The policy of the new company will be to market its products through the jobbers and a big publicity campaign is planned for the near future. The Auto Parts Company was started eight years ago with a single article for the Ford car and today manufactures a large number of specialties which are well known to the trade and owners. The Apco guarantee of satisfaction or your money back will be continued.



New Grinding Motor.

Illustrated herewith are shown cuts of a new low-priced electric grinding motor made by the U. S. Electrical Mfg.

Motor and Pedestal.

Co., Los Angeles, Cal. The machine is a high grade and effective one in every way, although low in price because made in large quantities by special tools. The machine is sold motor only for bench mounting, motor with pedestal, or motor with pedestal, guard, tool rests, water buckets, etc. It costs practically nothing to set up this tool. It is easy running and silent in operation. The motor is powerful but consumes but little electricity. Its ball bearings are mounted in a special housing with sealing rings that are proof against dirt and grit.

Motor with Pedestal, Guards, Tool Rests, Water Bucket, etc.

These bearings are standard in size, and readily removable for replacement in event of wear. The entire motor is totally enclosed. The spindles are heavy one-piece construction of the best grade of spindle steel. Convenient tool grinding rests are adjustable in any direction. The flanges are ample and are turned absolutely true on all sides to insure perfect balance and wheels running true. The water pot can be swung under the table out of the way. The heavy wheel guards are easily removable.

Two New Ford Car Attachments.

The Apco Mfg. Company, Providence, R. I., is marketing two new specialties for the Ford car; a horn button attachment and a flag holder. The horn button attachment should appeal to the Ford owners, as it enables the operation of the Ford horn without removing the hands from the steering wheel. The button is located in the center of the wheel as on high-priced machines, can be attached in a few minutes and comes with necessary wiring to make connections. The design is neat and sturdy, makes for decided convenience, and retails at 25 cents. The Apco flag holder holds three flags and in such manner that the flags are displayed to an advantage. The flag staffs are so crossed that the middle flag can be well displayed, and the holder can be easily attached to the filler tube which, being tapered, makes attaching the usual flag holder more or less work. The Apco design comes finished in black enamel and lists at 25 cents.

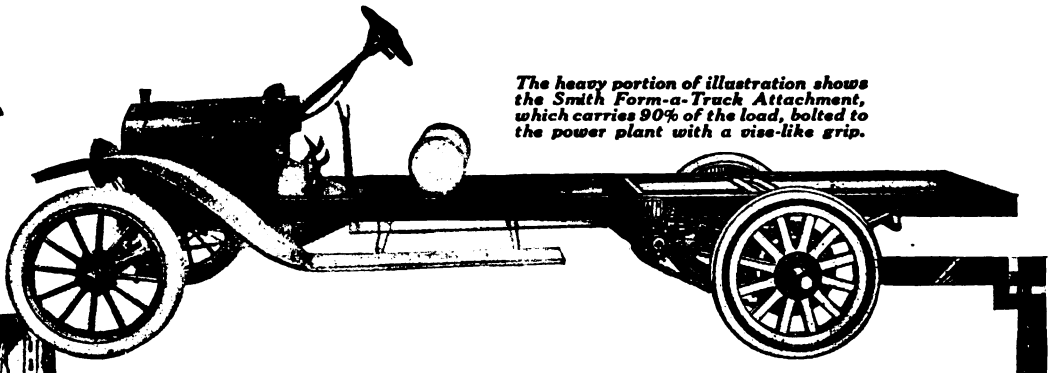
Monroe Car Price Increased.

The Monroe Motor Company has announced that the price of the Monroe has been increased to $1095. The Monroe Company has fought against increasing the price of their car just as long as it was possible. Long after all other high-grade comparable cars had increased their price the Monroe remained the same. However, the steady increase in the cost of materials and labor finally made it necessary to do one of two things—increase the price or decrease the quality. The latter could not be even considered. But in accordance with their usual policy of looking farther ahead than for the mere temporary profit the Monroe only increased the price to $1,095—which is nowhere nearly proportionate to the increased cost of production. The remarkable growth of the Monroe Motor Company bears testimony to the high quality of their product. Everywhere their dealers are sending in together with more orders enthusiastic reports not only in regard to the sale of their cars but about the wonderful satisfaction these cars are giving their owners.

A New Piston Ring.

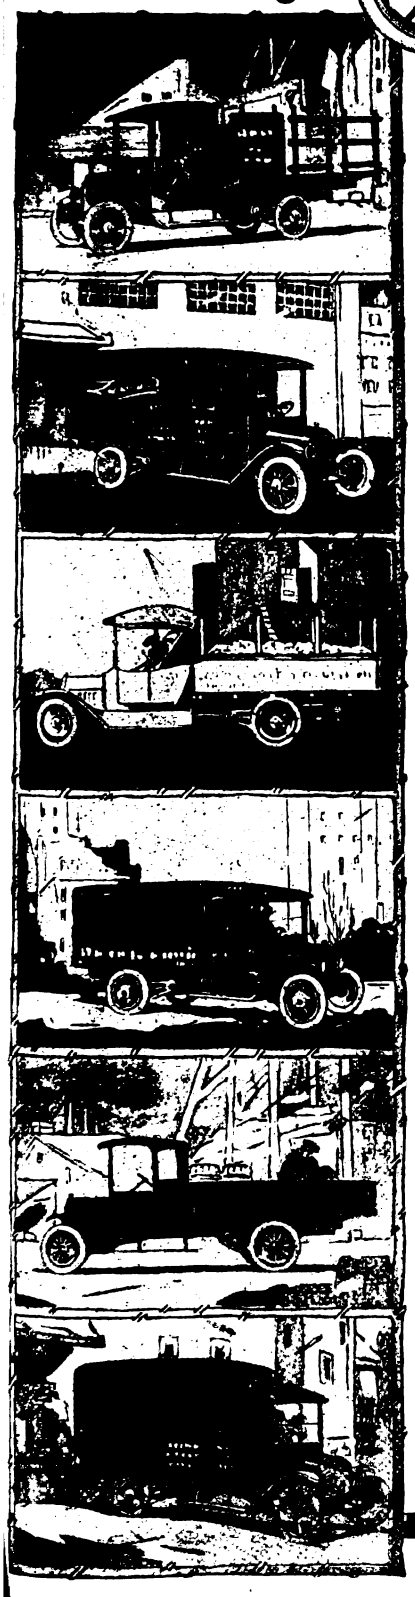
A new entrant into the piston ring field is the HarWard Manufacturing Company, 3939 Magnolia avenue, St. Louis, Mo. After a long series of practical tests and experiments this concern has developed a one-piece ring of unique construction as shown by the accompanying cut. The interlocking members of the joint engage in such a manner that no opening occurs in any direction through it, even when expanded to a worn cylinder. The inventor's idea in developing this joint was to get away from the long lap construction, thereby preventing gumming oil and carbon between its members, from retarding the free and quick movement of the ring in expanding and contracting to follow the varying diameter of the cylinder. The eccentric groove around the inside surface of the ring gives an important ad-

vantage but without sacrificing any of the edge bearing surface.



Two rows of separate oil pockets are cut into the outside surface for receiving and distributing excesses of oil which would otherwise pass upward into the combustion chamber. The heavy film of oil retained in these pockets is also for the purpose of giving high compression. The manufacturers consider this one of the most important features of their product. There are also one or two other features introduced into the ring construction, an important one of which is not visible to the eye, but is a certain quality put into the ring by a new process of manufacturing, which they have developed. The ring is covered by two distinct patents, with others pending.

New Fuel Generator.



The Duntley Gas Generator Co. guarantees that their new hydro-pneumatic gas generator will save more than fifty per cent. of fuel cost or the money paid for it will be refunded. This gas generator enables the use of a fuel of one-half kerosene and one-half gasoline at a cost of 14 cents per gallon. It handles this low-grade fuel with perfect com-

Smith Form-a-Truck $350 f.o.b. Chicago

The heavy portion of illustration shows the Smith Form-a-Truck Attachment, which carries 90% of the load, bolted to the power plant with a vise-like grip.

500% Increase in Dealer Profits Already in Sight

THE demand for Smith Form-a-Trucks in sight for the next eight months practically guarantees profits for Smith Form-a-Truck dealers 500% greater than last year—and last year Smith Form-a-Truck dealers made more money than any other dealers in the motor truck industry.

18,000 Smith Form-a-Trucks have been sold for immediate delivery in January, February, March and April.

Sales at this rate will demand a production of 60,000 this year, 500% in excess of our total production for 1916.

And if the increase which April shows over January keeps up, there is no end to the volume of business to be done by Smith Form-a-Truck dealers.

April sales are 800% in excess of January sales: 400% in excess of February sales: 100% in excess of March sales.

—and 50% of the production which at the start of this year we believed would take care of the entire year's business.

The 10,000 Smith Form-a-Trucks sold for April delivery is equal to the entire production for 1916.

And Smith Form-a-Truck dealers are getting the profits out of this huge business.

Territory is already at a premium. Dealers are being offered big cash bonuses for their sales franchise.

There is still room for big dealers who can qualify.

Many of the livest dealers in the industry—the biggest money makers—the men with the biggest reputations, have moved to new sections of the country where there was a Smith Form-a-Truck dealership available—they saw the real profits to be made.

If you are qualified to be a Smith Form-a-Truck dealer, this is the biggest opportunity you have ever had offered to you. Wire today.

Smith Motor Truck Corporation

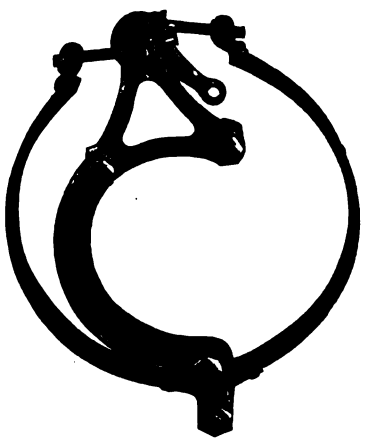
Southern Branch, 120 Marietta Street, Atlanta



Digitized by Google

bustion and eliminates carbon deposits. There is an absence of any gaseous odor or smoke or vapor. The motor operates on a superheated hydrogen and carbon-monoxide gas of unknown chemical analysis. The mixture, however, is known to possess very high heat units, which increases the power of the motor from 10 per cent. to 15 per cent., depending upon its condition. No vaporized fuel enters the cylinders and in consequence, there is nothing to carbonize or to work past the piston rings and deteriorate the lubricating oil in the crank case. It will be appreciated by motorists or owners of trucks; there will be less bearing troubles. The valves will rarely require grinding in, except at long intervals. Rings, wrist pins and bearings will have lengthened life, and motor repairs will be reduced to a minimum. The motor runs cooler and spark plugs maintain clean and bright firing points which rarely ever require attention.

For full information, address the Chicago Pneumatic Tool Co., 1615 Michigan avenue, Chicago, the sole distributors.

Emergency Ford Car Brake.

There has long been need of a good emergency brake for Ford cars, as the present internal cast-iron brake is inefficient and becomes worn to practically uselessness after two thousand miles' running, when it rattles, allows the car to creep when being cranked and refuses to hold. The Holdford brake can be applied in place of the external brake in a very short time, as there are no extra attachments used or holes to be drilled,

Holdford Brake.

etc., and after the first adjustment will wear the lining completely out without readjustment and will positively lock the wheels instantly, if desired, on any hill, with any load. The foot service brake on a Ford car, when used to any extent as on light trucks, delivery wagons or for general city work, causes 75 per cent. of the trouble on the rear ends, as all the strain is applied through the transmission. The Holdford brake is applied to the outside of the brake drum without displacing the old internal brake and connected to the foot pedal by means of an equalizing bar, relieving the transmission of all this strain and furnishing a positive brake at all times. Made by the G. H. Dyer Co., Cambridge, Mass.

Brake Lining Sales Made Easy.

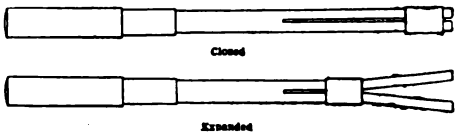
How to keep a stock of brake lining in shape and make sales quickly and easily has been a problem to garage men and accessory dealers. To handle a good-sized roll of brake lining is a job in itself. And to keep the sizes in stock that are wanted most is almost impossible when the rolls must be stacked up in one corner of the room or other out

of the way place. The new brake lining display rack shown here has just been issued by General Asbestos & Rubber Company of Charleston, S. C. It is designed to hold seven rolls, and a rod put through the center allows the rolls to revolve very easily and make it easily possible to measure off the exact length needed. The company is prepared to furnish these racks stained in either mission, mahogany or oak to match the balance of the fixtures in the store where they are placed. This Garco display rack is strongly constructed and should easily last through years of use. It is bound to speed up your sales because it displays brake lining where your customers can easily see it. A glance will tell you whether or not you have in stock the sizes you need—every sale can be made in one-tenth the time required without such a display rack to keep your stock in shape. This display rack is but one of the long line-up of sales helps sent free to Garco dealers. The cost of producing this feature has necessarily limited the number that will be distributed and it is very possible that prompt action is necessary if you are to secure one of these for your store.

First-Aid Outfit.

In this issue will be found an illustration, with a description, of a first-aid outfit which every motorist should carry. It consists of a strong metal case made of heavy bessemer steel, 11½x5½x2¼ inches, finished in black baked Japan and fitted with a strong instantaneous snap. Full particulars as to the contents of the outfit will be found in our announcement in this issue. Such an outfit may be the means of saving your life some time or other, or the life of some friends. The cost is $2.50, but we have made an arrangement with the manufacturers of such a character that we can supply the Automobile Dealer and Repairer for a year and this outfit for the price of the outfit, that is, $2.50. Those who have already subscribed can have one of these outfits for $1.60 and remittance can be made by check, money order, or in any convenient way. Address Motor Vehicle Publishing Company, 71-73 Murray Street, New York City.

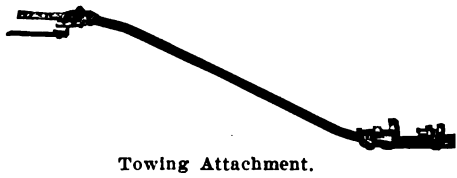
A Charming Health Resort.



If any of our readers are under the weather and want to spend a few weeks recuperating, we know of no place where this can be done to better advantage than at the Walters Sanitarium, Walters Park, Pa. This institution is located on a hill, overlooking a magnificent valley. The air is about as pure as the air can be. Dr. Walters, the proprietor, has achieved great results in the past forty or fifty years at his sanitarium, which has had to be enlarged several times to accommodate patients. Any man who is run down and wants to build his health up can do it at this institution in a very satisfactory manner. An elegant illustrated booklet, giving full particulars, will be sent to any one who will write for it. Our subscribers who are physicians in some cases could send convalescent patients to the Walters Sanitarium to advantage.

Little Giant Starter for Ford Cars.

Many of our subscribers who are owners of Ford cars will be interested in the announcement on another page of the Little Giant Starter Company, Canton, O., manufacturers of the Little Giant Starter especially for Ford cars. Particulars will be sent to anyone who is interested enough to write. This company wants agents to sell their starters and our subscribers who are dealers and repairmen should write for special terms to agents.



Useful for Garages and Repair Shops.

The G. H. Dyer Company, 155 Brookline street, Cambridge, Mass., make a useful bushing extractor for Ford cars.

Bushing Extractor.

It will remove steering knuckle, spindle arm and spring bushings in a jiffy. It will pay for itself in a few minutes. The price is $1.25. This firm makes

Towing Attachment.

also a good towing device. It steers the car that is to be towed and can be attached in one minute. It is a time saver and a money maker. For further information address the manufacturers.

"Story of the Automobile."

This little book is as interesting as "a tale that was told." It gives the history of self-propelled vehicles from 1760 to the present year. It has 300 pages illustrated with charts and comparative tables, is bound in cloth, and is sold for $1.50. It may be found with leading booksellers, but if you are unable to procure it address the publishers, A. J. Munson & Co., Great Northern Bldg., Chicago, Ill. A limited and abridged edition of this work is offered free as long as the copies last. They will soon be exhausted, however, and you should write quickly in order to get one.

$1195
Mitchell Junior—a 40-h. p. Six
120-inch Wheelbase

Mitchell SIXES

$1460
7-Passenger—48 Horsepower
127-inch Wheelbase

Trust Mr. Bate

All sorts of arguments are offered on motor cars today. But men will do wisely who trust Mr. Bate.

John W. Bate is a great efficiency expert, and a great engineer. He has spent 14 years on the Mitchell.

This entire factory—covering 45 acres—was built and equipped by him. He has spent millions of dollars to equip this plant to build this one type economically.

He builds 98 per cent of the car here. Our new body plant builds the bodies—all under ideal methods.

Nobody else can build a like car at like cost. Any comparison will prove that.

Note the Extras

This factory saving shows in our extras, which cost us this year about $4,000,000.

31 Unique Features—
24 per cent Added Luxury—
100 per cent Over-Strength.

No other car is so complete. No other car at near this price is so handsome or so strong.

His Final Cars

The latest Mitchells show the final results of all Mr. Bate's revisions. He has worked out more than 700 improvements. He has added every extra that seems desirable. He has added 24 per cent to the luxury cost, out of our body-plant savings.

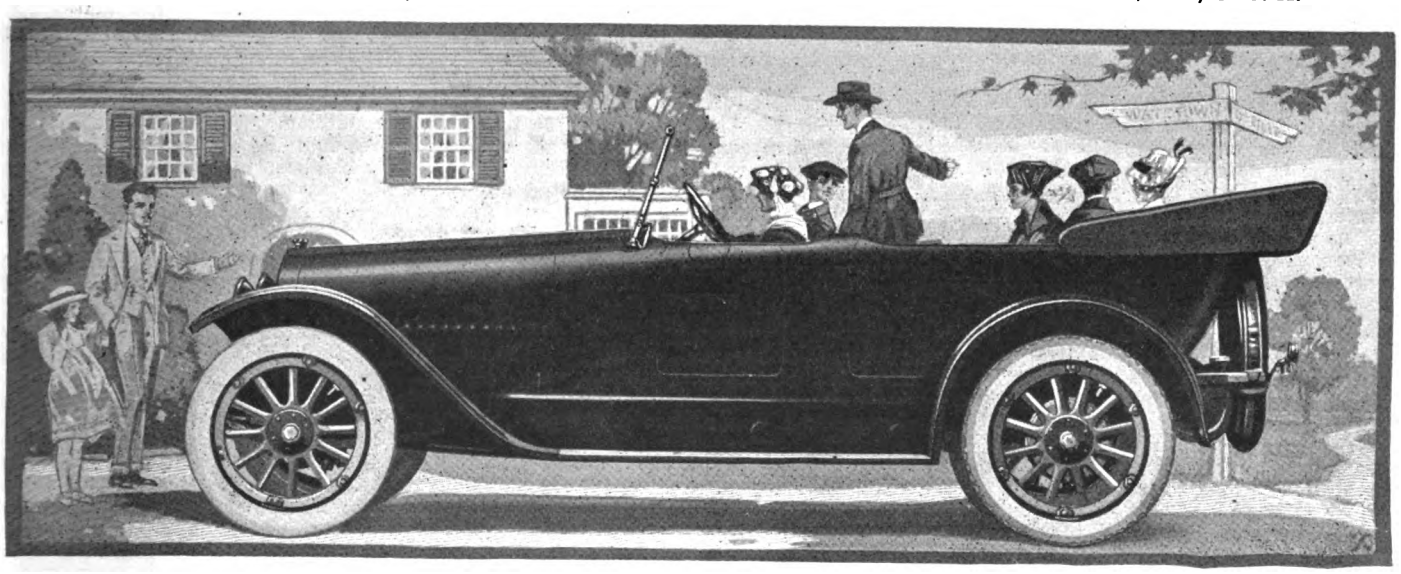
Over 440 parts are made of toughened steel. All safety parts are oversize. Vital parts are built of Chrome-Vanadium. Gears are tested for 50,000 pounds per tooth. Engines for 10,000 miles without wear. And in two years not one Bate cantilever spring has broken.

TWO SIZES

Mitchell—a roomy, 7-passenger Six, with 127-inch wheelbase and a highly-developed 48-horsepower motor.

$1460

Four Passenger Roadster, $1495. Sedan, $2175. Cabriolet, $1895. Coupe, $1995.
Also Town Car and Limousine.



Mitchell Junior—a 5-passenger Six on similar lines, with 120-inch wheelbase and a 40-horsepower motor. ¼-inch smaller bore.

$1195

All Prices f. o. b. Racine

Buyers know these facts. A million dollars will be spent this year to tell them. We want to hear from dealers who like the Mitchell prospects.

MITCHELL MOTORS COMPANY, Inc.
Racine, Wis., U. S. A.

Frackto Kloth Will Cost More.

The Davis Chemical Mfg. Co., 306 Warren avenue, Brockton, Mass., announce that commencing July first the price of their well known Frackto Kloth for windshields will be advanced from 35 cents to 50 cents, this increase having been rendered absolutely necessary by the much greater cost of materials used in the manufacture of this article. Those desiring to purchase should bear this in mind and send their orders in at once.

Special Offer on First Aid Emergency Outfit.

On another page will be found a full description of a first aid case for emergency use. Every man who runs an automobile should carry one of these cases constantly to provide for possible accidents. While it may be, of course, that he will never have a chance to use it, the time may come when it would be important enough to save somebody's life. We are offering this outfit (the price of which is $2.50) in a strong steel case, together with a copy of the Automobile Dealer and Repairer for a year for the price of the outfit itself or $2.50. Those who have already subscribed can have the outfit for $1.60 and remittance can be made by money order or in any convenient way. Address Motor Vehicle Publishing Company, 71-73 Murray street, New York.

Has Great Hauling Strength.

The Little Giant Convert-a-Car makes an interesting offer to dealers. This will be given by sending for particulars to the Chicago Pneumatic Tool Co., 615 Michigan avenue, Chicago. Your best interest as a dealer should cause you to write at once. It is an over-size and separate spring truck for connection with a Ford car, and is made in three sizes, 1-ton, 2-ton and 3½-ton. In addition to this, this firm provides a pneumatic gas generator which it is claimed will save over half the cost of fuel. This uses a half-and-half mixture of kerosene and gasoline with steam and air and gives more miles and more power for less cost. There will be a whole lot of these commercial bodies sold this year, and those who get into the business at once will reap immediate and large profits.

A Low-Priced Vulcanizing Outfit.

The Sunshine Light Company, Salt Lake City, Utah, make a complete outfit for vulcanizing which they sell for $1.50. With it vulcanizing may be done in five minutes and the work is guaranteed to last as long as the tube lasts. No experience is necessary to use this vulcanizer, and it not only appeals to the car owner, but to dealers it supplies a means of a profitable business in selling to others. Information can be had of jobbers or those interested can write direct to the manufacturers.

Send for a Free Sample.

Every reader of our magazine is entitled to a free sample of Golden Star Auto Body Polish. It is claimed this is the best cleaner and polisher on the market. It contains nothing to destroy or dull the finish, and is water proof and weather proof. It should be a big seller, and dealers should take up with it. It is made by R. W. Morris Manufacturing Co., Inc., Kansas City, Mo.

Illuminated Flag Holder.

Now that the feeling of real war is sweeping over the country, automobile drivers and owners insist on flying the American flag from their cars. Up to the present time most any crack or crevice in the front of the car, into which a flag stick could be put, has been pressed into this patriotic service. Inasmuch as the radiator cap is the logical place to put such an ornament, the Howe Mfg. Co. of Chicago, producers of the Howe spotlight, have introduced a specially made illuminated radiator flag—carrier with flag—that can be attached to any radiator cap. The light, necessarily a small one, is protected by a highly polished nickel plate deflector—shaped so that all of the light rays are put on the flag and no direct light rays are seen by

Illuminated Flag.

the driver. The flag is 6 inches by 8 inches, of high-grade silk. The ends are sufficiently protected so they will not slip out easily.

A clamp which will fit on any radiator cap holds the upright securely and affords a most convenient method of attaching a flag to the automobile. It is of special note that the motorist is in no way inconvenienced by this clamp. The radiator cap may be removed as often as desired without removing the flag or clamp. The clamp may be purchased separately, 35 cents, and will serve as ordinary flag holder.

This highly improved illuminated flag holder will be furnished completely with bulb, flag and wiring for $1.25, without bulb, $1.00, at all dealers and jobbers.

Remarkable Growth.

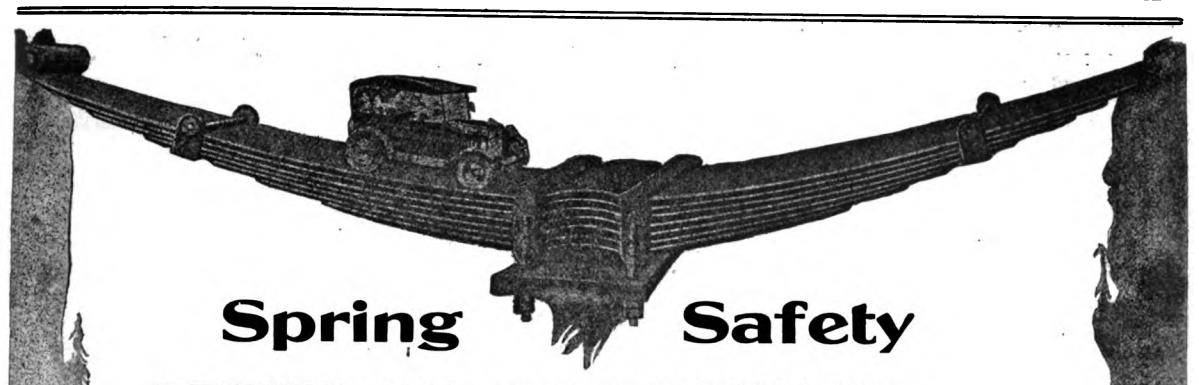
Production records of Fuller & Sons Mfg. Co., Kalamazoo, Mich., transmission makers, show during the first five months this year two and one-half times the output of the same period 1916. The new plants now being erected, which will be ready for occupancy along in the summer, will no doubt enable this company to make a very much larger increase in production for the corresponding period of last year.

Convert-a-Car.

The Chicago Pneumatic Tool Company, Fisher Building, Chicago, Ill., a $14,000,000 corporation, has an exceedingly interesting dealer proposition. They are now offering the garage trade their Convert-a-Car which is a super-size Ford truck-unit. It is noteworthy that this is a truck-unit, made by a truck manufacturer; that thousands of their Little Giant heavy-duty trucks are economically and dependably delivering all over this country, and in many places abroad. To this new field of Ford truck-unit manufacture, they bring a wide reputation and twenty-three years of aggressive experience in designing and building tools and machinery for engineering projects of every description. The Convert-a-Car is not a makeshift, but built up of such over-size standard units that it is an actual truck in construction and ability. A letter to the Chicago Pneumatic Tool Company will bring the progressive dealer or garage man some interesting facts and figures on the present truck situation.

Free Advertising to Dealers.

The Amazon Rubber Company at Akron, O., are the originators of a unique line of advertising material, all of which is furnished to the dealer absolutely free of charge. This includes newspaper advertising, outdoor bulletins and circular letters, without charge for either newspaper space or letter postage. Special road signs, lithographed stationery, business cards, etc., imprinted with the dealer's name, are also given him. One of the main features of the advertising is the outdoor painted bulletin. This bulletin is 8x32 feet long, painted in several colors, and stands for a period of three years. These boards are all erected for the dealer without charge for erection or rental.



Castor Oil for Motors.

Preparing for unlimited national expansion, the Sexton Oil Company has opened its new factory at North Chicago, Ill., which assures an output of 300,000 gallons per week without double shifts. A strong campaign will be carried on over the country for new business, which the concern will be able to handle with its increased facilities. The tremendous strides made by the company during the last year in the sales of its patented castor motor oil made it necessary to increase the factory facilities. "Probably no product ever placed on the market has ever met with the success that has marked the introduction of our castor motor oil," said President P. J. Sexton, "and our difficulty has been in keeping up with the demand. Castor, combined with the best mineral oils in the properly determined proportions provides a most efficient lubricant for an internal combustion engine and its heat registering qualities prevents the oil from breaking down under the heat of the engine."

More Light.

The Osgood Lens & Supply Company, 2021 Michigan avenue, Chicago, Ills., would like every dealer who is a reader of the Automobile Dealer and Repairer to write to them for some attractive sales data in connection with their new Osgood lens, which is said to throw waist-high light with no glare for one third of a mile.

Spring Safety

MOTORISTS know that their cars are no stronger or safer than their springs.

When a car owner comes in with a broken spring, don't sell another just like it—sell a safe spring and make the motorist a booster for you—sell him a

Tuthill Titanic Lubricated Spring

Guaranteed forever against center breakage—guaranteed at all points and in all respects for one year

Tuthill Titanic Lubricated Springs are *strongest* at the center—the place where seven out of ten spring breaks occur. **No weakening center bolt of center nib.** But a patented center arch and "wedge and yoke" plate, holding the spring leaves in a vise-like grip and making Tuthill Titanics strongly reinforced and unbreakable at the center.

Our Special Ford Front Spring carries the same broad guarantee.

Get your share of the big spring replacement business in Tuthill Titanics. More Tuthill Titanic Springs are used for spring replacement than all other makes put together. Easily adapted to any axle construction *without extra expense.*

Write to-day for valuable spring booklet and 1917 price list; the most complete price list ever published for spring replacements—also the name of the nearest distributor.

Tuthill Spring Co., 760 Polk St., Chicago

Where the Profits Are.

Take an ordinary auto repair job, one spring to be fixed. Say you charge $3 for your work. If of this, $1 represents material and the job takes 3½ hours; you are getting a little over 50 cents per hour for your time. No more. Take the same job. One spring to be fixed. But this time you will use Harvey Semi-Finished Repair Plates instead. Your material cost will remain $1, for Harvey plates cost only a trifle more per pound than spring steel and there is nothing like the waste. Now here's your real saving. Instead of 3½ hours' labor, you will cut this in half or less. But the job is worth $3 the old way and you are giving a better job with Harvey Plates. So instead of making 50 cents an hour, you are making $1 per hour. Instead of turning down work because you are too busy, you do twice the repair work. Give Harvey Semi-Finished Repair Plates a trial. A few dollars spent will prove to your value. They are made by the Harvey Spring & Forging Co., Racine Junction, Wis.

Subscribe to the Automobile Dealer and Repairer, $1.00 Per Year.

Storage Batteries Simplified. By Victor W. Page. The Norman W. Henley Publishing Co., 4 and 6 West 45th St., New York. Price $1.50.

This is a most thorough and authoritative treatise on the subject of storage batteries. It fully describes the Exide, Edison, Gould, Willard, U. S. L. and other storage batteries for automobile, stationary and marine work. Nothing of importance has been left unsaid that a reader should know about the practical operation and care of storage batteries. Instructions have been made as simple as possible. The book comprises about 200 pages, numerous illustrations and diagrams, and is well indexed.

Legal Points for Automobile Owners. By Leslie Childs. J. S. Ogilvie Publishing Co., New York. Price 50 cents.

This handy little book states briefly and concisely what every automobile owner should know regarding his legal rights and his liability under various circumstances It gives information regarding defense in arrest for speeding, the law on turning corners, rights of pedestrians, etc. The book is written in everyday language and is not in any sense a text book. An index is given in the front of the book and the information is boiled down to 55 pages.

Franklin Cars.

The Franklin Automobile Co. during the week of May 19, received more orders than in any previous week in its history. Factory production also reached a new high mark, 216 cars being turned out in 5½ working days.

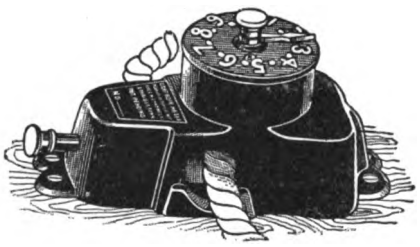
A New Ford Car Light.

A new Ford car electric light has been placed on the market that will no doubt be found valuable to those who desire something that is necessary for a low engine speed. It is called the "Lite-a-Ford." It strengthens the magneto current at slow engine speed and has a reverse action on high engine speed, causing the current to retard You can also dim the lights to any degree you desire when driving in the city or meeting other vehicles. The timer is a rheostat which instantly times the lights to any degree by the simple turning of a knob. This device gives all the advantages of a high-priced lighting equipment and it costs but $2.50. It has received high endorsements and the purchase price is cheerfully refunded if not fully satisfactory. It is made by the Hastings Manufacturing Co., Hastings, Michigan.

New Development in Bench Drills.

Probably there is no phase among the manufacturers of tools that so clearly voices the development of modern shop requirements and of the individual demand of the workman as the slogan, "Make Better Mechanics." Today we have tools and machines common enough in every garage or repair shop that evidence the insistent demand for accuracy in results and for time saving, "speed up" necessities of the modern workshop. Every man who has many drilling jobs to do knows the need of an efficient bench drill, but up until now no great development in this useful tool or machine has been made. But now with the production of the "Yankee" bench drill we have one that in every particular part shows an extraordinary improvement over the type with which we have been familiar. Strength and rigidity have been secured by scientific design, and not through bulk of material, thus ensuring economical lightness in the construction of its mass. Besides, the



Yankee Bench Drill.

remarkable care and precision in the construction of the various details, special features have been incorporated in the "Yankee" bench drill which stamp it as a tool of high efficiency. In the one feature of the automatic friction and ratchet feed we see markedly the modern tendency of the elimination of the personal equation of the workmen. The feeding of either large or small drills is not left to the judgment of the man on the job. He cannot feed the "Yankee" bench drill so fast that he smashes his drills or so slow that the amount of time consumed on the job is in excess. Uniform and regular feeding goes on until the job is finished.

A Unique Measure

It is no longer necessary to search all over the store looking for a yardstick or tape measure. Every time you sell a rope, garden hose or tubing of any sort, a little instrument called the Gant Meter prevents over and under meas-

Gant Meter.

ure and it is simple and quick of operation. It ought to be in the equipment of every well equipped store, garage and electrical supply house. It is sold by John E. Chumbley & Co., Nashville, Tennessee, who are general distributors.

A New Brake Lining.

It is well known that neglected brake linings are liable to cause a serious accident. The TesTbesTos is made of the very best quality of asbestos, carefully inspected, thoroughly and scientifically manufactured and gives long and satisfactory use. All this can be substantiated by the testimony of those who use it. All the firm asks is a trial, and they are sure that this will soon cause it to be used almost universally. An elaborate and unique folder is being sent out to dealers and no one should fail to send and get it immediately. It can be had for the asking, and at all events when the one who asks sends his business card with his request. This circular gives a good deal of valuable information both in relation to brake linings and to the best method of making money by selling them.

Victor Ford Car Heater.

The Crew Levick Co., Real Estate Trust Bldg., Philadelphia, have taken over the general sales agency of the Victor Heater, 105 Erie St., Camden, N. J. The heater as marketed will be virtually the same as shown at the automobile show only perfected in some details which will be described in a later issue.

New Dealers' Association.

The first steps in the formation of the National Automobile Dealers' Association were taken in Washington, D. C., by the representatives of a number of associations in the large cities, who were there opposing the proposed 5 per cent. tax on automobiles.

A committee has been formed, of which G. W. Brown, Milwaukee, is chairman. E. T. Conlon, secretary of the Grand Rapids Association, is secretary. This committee will get in touch with all the associations throughout the country to arrange for a general organization meeting before August 1. At that time the work will be perfected, and permanent officers chosen.

The Hansen Manufacturing Co., Cleveland, Ohio, makes some unusually desirable automobile accessories. One of these is an automatic air valve. It will commend itself at once to those who know anything about such things. There are models for garages, tire service and gasoline stations. In fact it is useful wherever air is used for filling tires. The Hansen hose clamp is easy to adjust, holds absolutely in place, will not leak and is comparatively inexpensive. If you wish to learn more about these devices write to the firm and they will be glad to give you full information.

A New Flag Device.

The illustration shows one of the five new patriotic emblems just created by Gus Balzer. Consisting of a light metal painted auto wheel, with four artistically waving celluloid flags surmounting the same, which are soldered right

into the wheel (size 7½ inches over all) and is clamped around the spout of the radiator. The wheel revolves on a metal axle by the slightest air pressure. It retails for only 50 cents, and is made by the Gus Balzer Co., 1777 Broadway, New York.

A New Differential.

The Miller Transmission Company, 90 West Street, New York, make a new differential which is said to be of real advantage under every and all road conditions. It transmits the power equally to both wheels alike no matter what the traction surface of either wheel may be. It is a gearless differential and is thus practically free from wear. The assembly is simple and has successfully passed exhaustive road tests. A circular giving full information will be sent to anyone interested, by applying to the manufacturers. It might be well likewise to send detail blue prints of the rear construction of your car in order to enable the firm to know just what you need and what it will cost.

A Mile in 38 Seconds.

A new straightaway mile record for 230 cubic inch class was recently established by a Chalmers stock chassis, with fan removed. Joe Dawson, the racing driver, now a member of the Chalmers experimental department, piloted the Chalmers on its record dash on the Atlantic Beach, Jacksonville, Florida. The Chalmers covered the mile in 38.1 seconds, under the observation of Joseph Tracy, technical representative of the American Automobile Association. Fred J. Wagner, the race starter, timed the event.

New Automobile Accessories.

Illustrated herewith will be found four useful accessories for the automobile. Fig. 1 is a novel rear tire holder to fit the demountable rims for Ford cars. As will be seen, it is designed to carry one or two tires on demountable rims. The

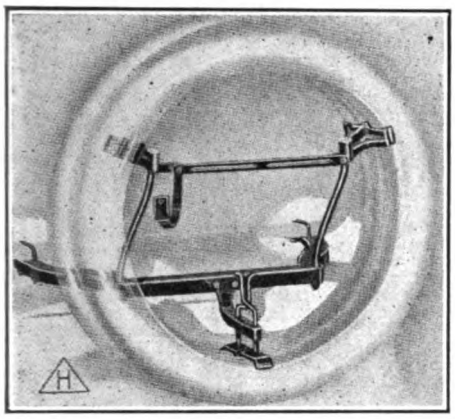

Fig. 1.

tires are rigidly held without the use of troublesome attachments and they can be locked to prevent theft very easily. The design is handsome and of good material. Fig. 2 shows a steel lined

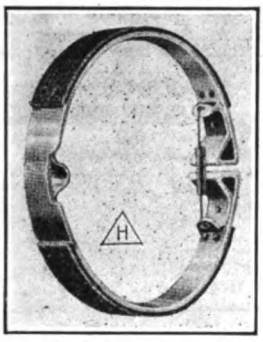

Fig. 2.

brake shoe for Ford cars which is absolutely indestructible. It provides an efficient brake, being lined with a fine quality of asbestos brake lining. The

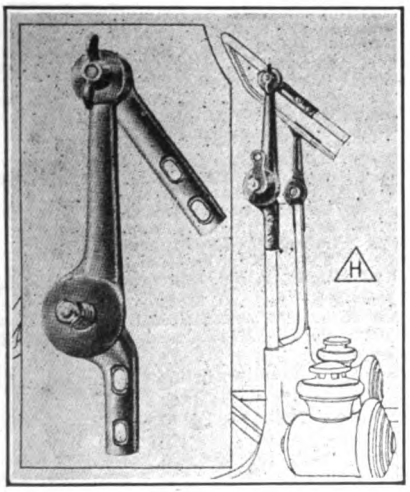

Fig. 3.

price for a complete set of these brake shoes is but $2.00. Fig. 3 illustrates a wind shield attachment. It is easily and quickly applied, requiring no holes to be bored or other changes. It is designed to replace the hinges originally supplied on a Ford wind shield, and insures safety and comfort in all kinds of weather. Fig. 4 is a foot accelerator. It can be applied in a few minutes without boring holes or otherwise marring the car, and permits complete foot control. All these accessories are for Ford

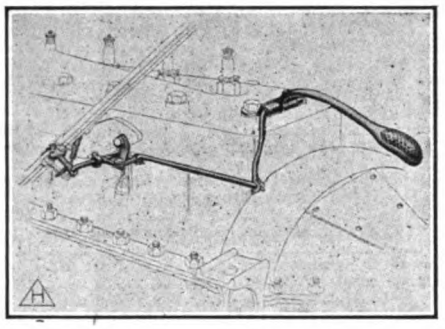

Fig. 4.

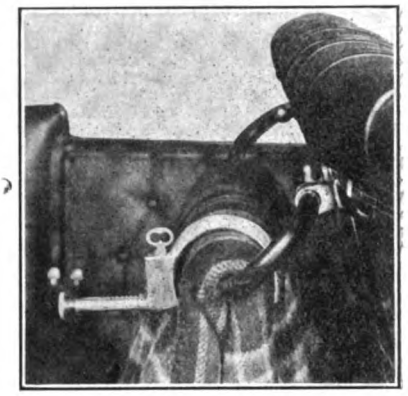
cars and with a good many others they are made by an enterprising and growing firm which will be glad to send catalogue to anyone writing for it, by addressing the Humboldt Machine & Stamping Company, Long Island City, N. Y.

New Portable Air Tank and Pump.

A complete, compact and handy outfit for garageman and dealer is the new portable air tank and pump recently put on the market by Black & Decker, of Baltimore, Md. A substantial air tank, fitted with a No. 2 Lectroflater Air Pump, is mounted on a strong cradle base, supported by two large wheels and one large swivel castor. A comfortable pushing handle is attached to the compressor



Air Tank and Pump.

platform, and the outfit is very easy to steer and handle. It is fitted with rubber tires, when for use on hardwood or tiled flooring. When emptied, the tank may be wheeled to the nearest electric connection (either current) and left there to refill itself. An automatic switch cuts off the current when proper pressure is reached. One of the big advantages claimed by its manufacturers for this outfit is that its piping and vital parts are thoroughly protected against injury from bumping into cars and other objects, thus preventing leaky joints. This outfit is also extremely useful in machine shops and factories, for blowing dust out of motors and generators.

A Dependable Motor Lock.

Although improvements are being made in almost every channel to combat the ingenuity of thieves, they themselves seem to progress about as rapidly as the ingenuity of honest people. The manufacturers of the Lap Robe Lock claim, however, that it is impossible to steal anything when their lock is used, it being not only strong, but impossible to

The Robe Lock.

pick. The malefactor will surely pass along when he sees how the car is protected by it. Automobile robes and the garments of its occupants are safe and secure when this lock is used. The lock is furnished with two keys and no two sets of keys are alike. It retails for $1.75. It is made by the Robe Lock Co., Inc., Oakland, Cal.

Scores Hit With Cork Insert.

The Advance Automobile Accessories Corp. of Chicago, makers and merchandisers of Cork Insert Transmission linings for Fords has made a remarkable record for getting distribution quickly. Mr. Harvey Cory, President of the company explains, "that no unusual methods of merchandising were used. We didn't put on a 'flying squadron' of salesmen—do any excessive advertising or anything like that. Our advertising department prepared a circular describing the Cork Insert Lining—showing the corks painted in natural colors in the lining. This strong circular supplemented by a letter—was sent to a picked mailing list of some 300 jobbers. The talk was so straightforward and so convincing that 33 1/3 per cent. returns were had and all contained orders. The good qualities of Cork Insert were instantly apparent. Nothing could have been stronger than showing jobbers just exactly how the corks looked in the linings."

This new idea of putting cork in transmission linings for Fords is just what that car has needed to take out the jars and jumps caused by the transmission grabbing.

$5,000 Prize Contest.

Our dealer subscribers should write at once to the Marvel Accessories Mfg. Co., 7233 St. Clair avenue, Cleveland, Ohio, for full particulars of the new $5,000 prize contest which they have inaugurated with respect to their Marvel Jr. Vulcanizer, and mention this paper.

Automobile Trunks to Order.

S. C. Simon & Co., 404 Brown Street, Philadelphia, are expert builders of automobile trunks. They have a good many different styles in stock and will build anything desired to order if requested. The prices are low and their product is guaranteed of the best. They also make hood and radiator covers, clamps to the wind shield to cut out the wind and rain, and a rear window light in case the one on the car happens to have been broken. They also manufacture other useful accessories, descriptions of which will be cheerfully forwarded if the reader will write for a catalogue to the above address.

Special Request

¶ IN writing to advertisers for circulars or information, you are earnestly requested to mention in each case that the advertisement was seen in the "Automobile Dealer and Repairer." By so doing you will confer a favor on both publisher and advertiser

GARAGE

LET ELECTRICAL ADVERTISING BRING BUSINESS TO YOU—

A Flexlume sign with its strong, raised letters throwing light down the street for many blocks is the most result-producing advertising within reach of the garage man or the dealer.

It will bring business to your door.

It will make your location stand out as a landmark on the street for it is impossible to overlook a Flexlume.

Flexlume characters are clear, unbroken. They are made of raised white glass with the illumination behind them, arranged in such a way that practically none of the light is lost.

A Flexlume transmits all of its candle power, and the clear, unbroken letters give the sign a greater reading distance than the others.

Besides all this a Flexlume has an atmosphere of distinction.

Yes, a Flexlume is the most efficient night sign, but it is a day sign too. Its solid, raised white letters standing out from a dark background give it the strongest possible daylight display.

And Flexlume signs are not costly. They can be bought on easy payments where cash is not available.

There are special Flexlume designs for most of the leading cars.

Fill out this coupon and get a sketch showing how your sign will look.

Make a PROFIT on your Tire Changes

The WEAVER UNIVERSAL Tire Changer

Will Handle the Old Rusted Tire and Rim as Quickly as the New

THE "profits" on tire changes are measured by the rapidity and ease with which the changes are made. With one of our Universal Tire Changers installed, your men will no longer have to spend from one to two hours "fighting" with some difficult tire. Rusted and corroded tires or battered rims consume no more time on this wonderful machine than the new tire and rim right out of stock.

The saving in time and labor will pay for this equipment in thirty days.

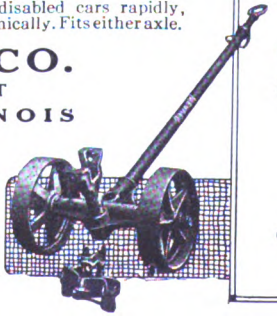
No Injury to Tires or Rims

Your customers will also appreciate having their tires and rims handled by SMOOTH ROLLERS instead of with a sledge hammer and cold chisel.

Every operation is performed by rollers—there is no springing or "battering" of rims and no cutting or marring of tires.

Will Handle Any Rim

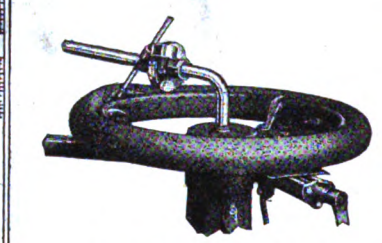
Any size or style of rim or pneumatic tire can be handled on this "Universal" Tire Changer. The adjustments are quick and simple. Weight 250 lbs., a REAL machine. The price will agreeably surprise you.



Valveless Bucket Pump

Will handle oil and soft grease in "three ways—true of no other grease gun.

Auto Ambulance



For towing disabled cars rapidly, safely and economically. Fits either axle.

Do You Get 10,000 Miles Per Tire

War times are economizing times. Motorists everywhere are not only making their own tire repairs, but they are also treating their casings to get more mileage from them.

TIRE-DOH sales have jumped by leaps and bounds since motorists are learning the value of TIRE-DOH when used to

TIRE-DOH-ize Outer Casings

"Every well made tire should give at least 10,000 miles of wear," said an experienced tire man recently. "And it would give that wear with proper care," he added.

"Proper care" means keeping the tires well inflated and "touching up" the casings regularly with TIRE-DOH. By filling the little cuts, holes and sand blisters with TIRE-DOH, the main cause of big tears and blowouts is overcome.

Best Repair for an Inner Tube Tear

Ten thousand dealers are recommending TIRE-DOH for repairing punctures, blowouts and inner tube tears—large and small. They know that it will make permanent repairs without the need of heat or tools—without danger of burning or overcuring the rubber. And they know it will fix torn-out valve stems and do other difficult jobs impossible by other methods.

Not a Tire Filler

TIRE-DOH is not a substitute for air. Neither is it an ordinary patch. It is a rubber compound made by a secret process. When applied, it becomes an actual and permanent part of the tire, firmer and stronger than the rest of it, and never comes off. Seven years on the market and a proved success.

For Motorcyclists and Housewives, Too

TIRE-DOH saves time, trouble and money for bicyclists and motorcyclists as well as motorists. And it also repairs rubber boots, hot water bags, etc. Thousands of users keep two outfits always on hand—one in the repair kit and one in the home.

Complete Outfits, 50c and $1.00

Canadian prices, 65c and $1.25. Everybody needs TIRE-DOH—over 750,000 "kneaded" it last year. This year our powerful national advertising campaign will tell the merits of TIRE-DOH to over thirty million people.

Motorists and others who cannot obtain TIRE-DOH from their dealers should order direct from us, and send us the name of their dealer.

Manufactured and Guaranteed by **ATLAS AUTO SUPPLY CO.** 616 W. Austin Ave. Chicago, Ill.

All Jobbers Sell TIRE-DOH

The Buyer's Interest in Wasteless Advertising

BUYERS who appreciate that waste in selling must eventually be passed on to them in some form, are paying more and more attention to the sales methods of the concerns seeking their business.

The extravagant use of space in publications of general circulation, to advertise a commodity or a service appealing chiefly to a certain well-defined class, is not only poor judgment, but *it is an economic waste.*

Can you imagine an intelligent salesman, with a proposition for a steel mill or a dry goods store, calling at every office in town in an effort to locate a prospect? How needlessly wasteful to adopt similar methods in advertising, which is simply an improved means of accomplishing certain necessary steps of a sale.

On the other hand, the seller who uses the business papers reaching *only* the class interested in his message, is employing the most direct, efficient and economical method of getting in touch with prospective buyers.

Properly used, the good business paper bears the same relation to the sales department, that an improved machine does to the production department. Better selling methods go hand in hand with better manufacturing methods.

To encourage wasteless advertising, the most efficient modern means of bringing buyer and seller together, there is every reason why the discriminating buyer should give preferred consideration to the concern that tells its business story in the buyer's own business paper.

Ask this office anything you want to know about Business Papers or Business Paper Advertising.

A Bumper for the Front and Rear of Every Car

The prevalence of extended front aprons and the great variation in fender aprons and frame construction now necessitate corresponding variations in Bumper designs to fit all cars.

In the Halladay Line we offer such variation with the least possible complication of parts.

The Dealer in Halladay Bumpers can be prepared to meet all demands and turn all prospects into buyers without a great investment in stock.

Our standardized models are the nearest possible approach to universal equipment and we manufacture special models for the few cars requiring such equipment.

Bumpers are the best selling Automobile Accessory of to-day and the Halladay Line is the best selling, most profitable and most satisfactory line of Bumpers.

Wise dealers: reflect and get busy.

Making Good on 138 Different Pleasure Cars and Trucks

SUNDERMAN $5
Vacuum Carburetor

F. O. B. Newburgh $6.50 for other than Ford or Metz

At the left we print the names of 138 different makes of pleasure cars and trucks on which a Sunderman Vacuum Carburetor has been installed.

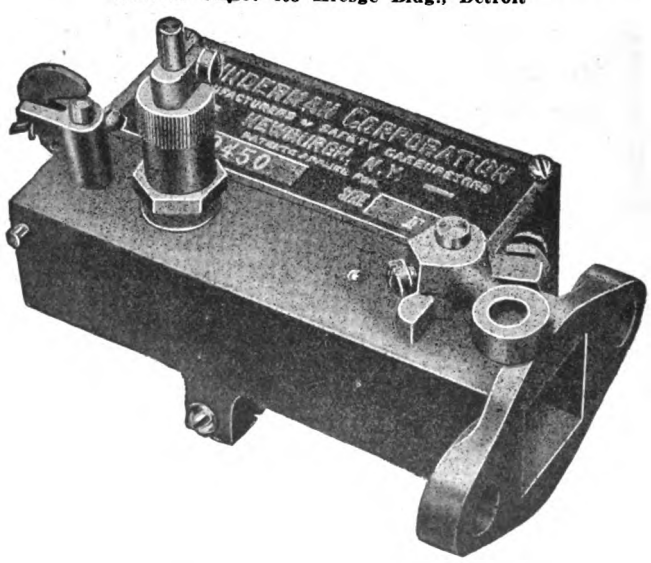
The great majority were replacements. Their owners wanted a new carburetor because old motors and imperfect carburetion were causing power drains and low mileage per gallon of gasoline.

Replacement business is the bitterest, most brutal and at the same time the most unfair test to which a carburetor can be put. Despite these handicaps the Sunderman Carburetor has made good on all makes of cars and thousands of testimonials prove it.

The Sunderman mixing principle and its simple construction furnish the reason. They prove that

THE SUNDERMAN IS THE CARBURETOR OF UNIVERSAL APPLICATION

When any other carburetor can stand up under such a test and deliver the same herculean power on the same miserly consumption of gasoline—then, and *not until then*, will we admit that we have a worthy competitor.



Owners, send your orders in now.

Manufacturers, doesn't this advertisement give you food for thought?

GOOD TERRITORY AND GOOD PROFITS FOR LIVE DEALERS WHO WRITE AT ONCE

DREADNAUGHT TIRES

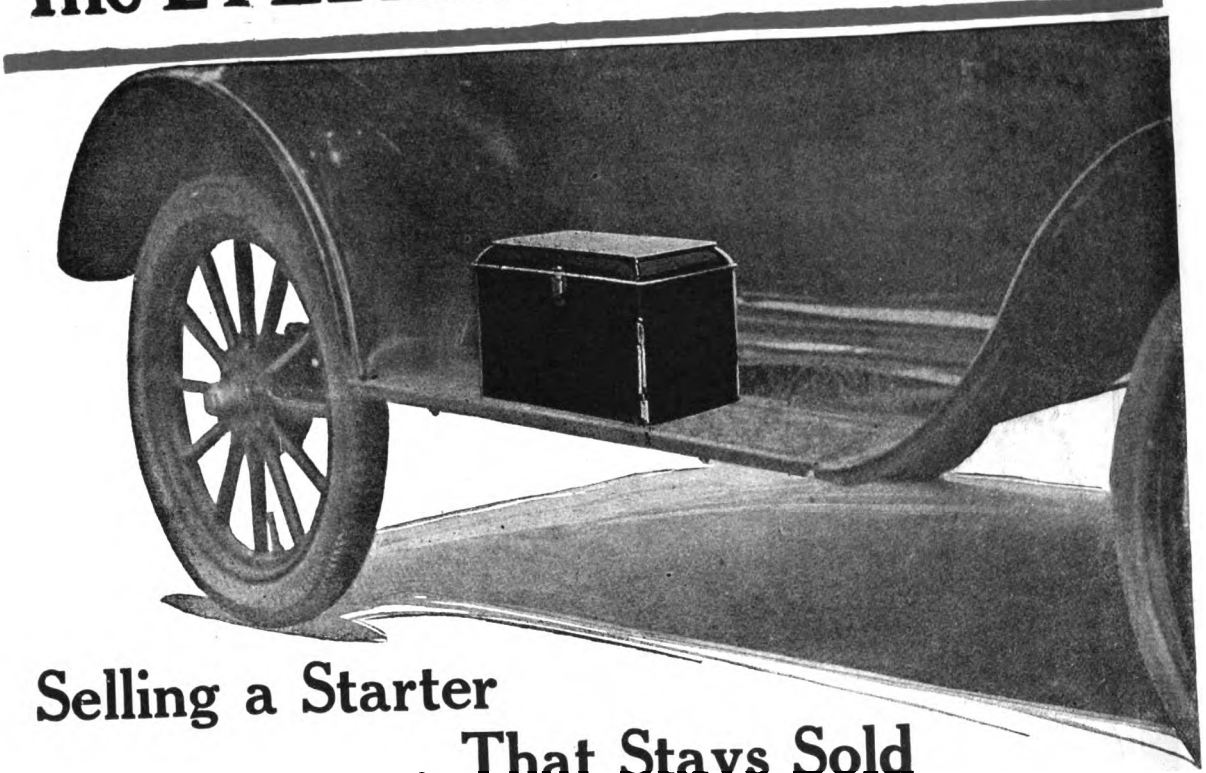
OUR latest Dreadnaught Battleships, the most powerful afloat, are armed with 14-inch guns which carry over twelve miles. The DREADNAUGHT TIRE is the sturdiest and smoothest riding and carries the automobile furthest without roadside delays.

5,000 Miles Guaranteed

DREADNAUGHT TIRES best withstand the ruthless grind of the road. They are made with two red rubber treads—"Vacuum" and "Ribbed"—and with the soft-toned ivory side walls they add smartness and distinction to the car, combined with the utmost economy. *Sold through dealers only.*

MANUFACTURED BY
The Dreadnaught Tire & Rubber Co.
Baltimore, Maryland

Beautifully illustrated booklet "The Evolution of the Battleship" by Henry McDonald Spencer, sent free on request.



DEALERS

We have an exceptional proposition to make you in open territory. The name of the tire will be an asset. We assure excellent service and protection in your territory, with intensive co-operation from our organization. Write or wire.

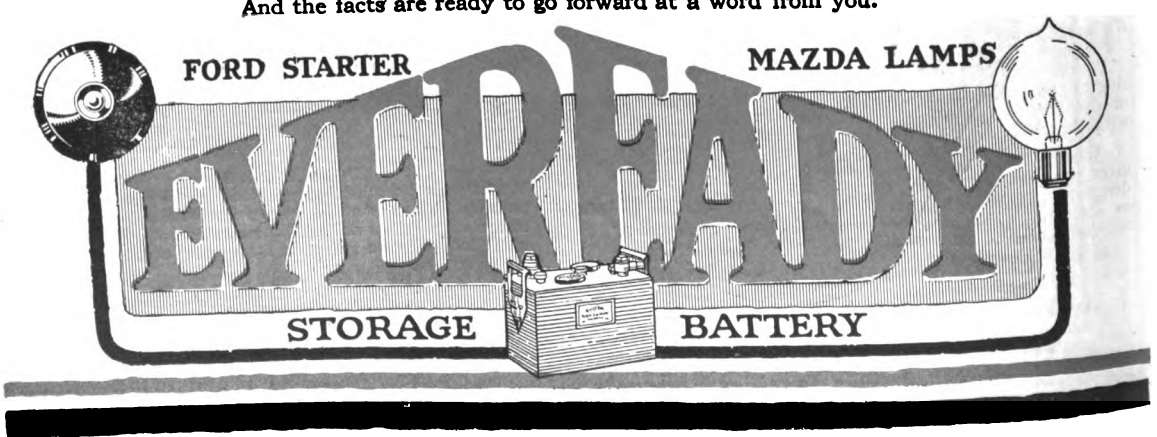
The EVEREADY Starting and

Selling a Starter . . . That Stays Sold

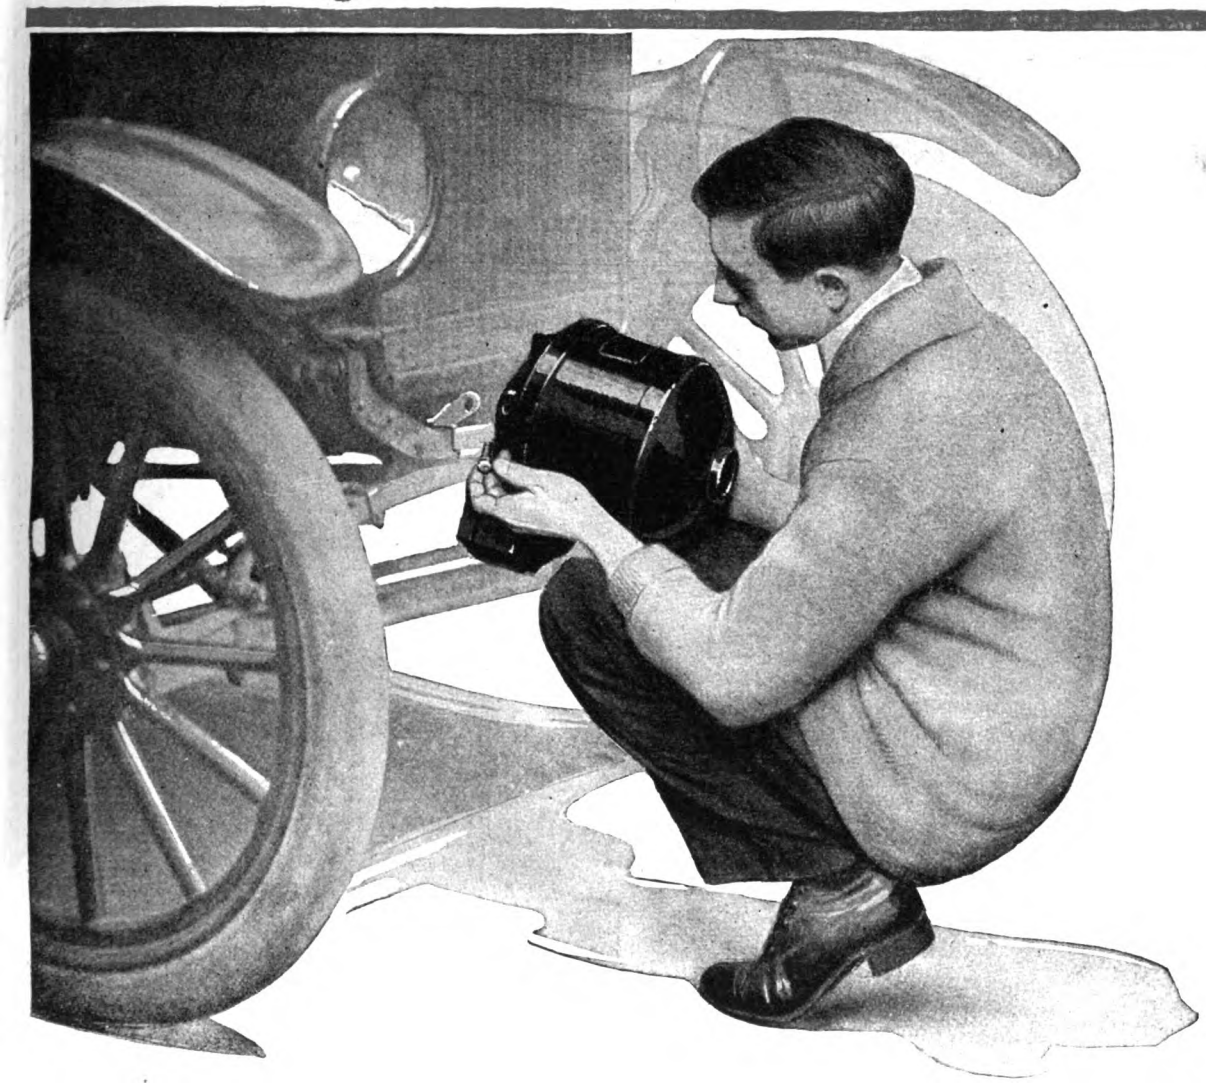


You may sell a starter today and at a fair profit. But what is left of that profit a few months from today when the purchaser continues to bring the starter back for repairs and adjustment? And what happens to your customer's good-will when you sell him a starter that will not stay sold?

Three years were spent in perfecting the Eveready Starter before it was ready for distribution. Three years spent in selecting and rejecting before it was placed in your hands.

And now you have it—to sell, and when sold, to ***stay*** sold.

* * *



Our distribution is now being carried out. There are a number of exclusive territories for an equal number of live dealers. And the facts are ready to go forward at a word from you.

Please mention the Automobile Dealer and Repairer when writing to advertisers.

Lighting System for FORD CARS

—specially designed for three point Ford Motor suspension

THE Ford motor is balanced on the Ford chassis with the weight of the engine resting evenly on all three points of suspension. So if you place a starter on either side of the engine you add considerable weight on one side of the front suspension point, throwing it out-of-balance with the other two points of suspension.

And this increased weight under vibration of road travel, gives the support at the front point of suspension, the tendency to sag, throwing it out of alignment with its bearing on the front cross member and impairing the flexibility of the entire power plant and forward part of the Ford chassis.

In the Eveready System, the motor-generator is mounted outside on the front cross channel member of the Ford chassis, and is coupled direct to the Ford motor shaft.

In this way there is no added weight on the engine support. Nor is the balance of the engine affected in the least. This is a claim no other system can make and it is important because it affects the whole life of the car. And what's more, being mounted in front of the car, cooling of the engine is not interfered with, and both the motor and Ford starting engine are always instantly accessible.

A folder has been prepared describing in detail the features of the Eveready Electric Starting and Lighting System for Ford Cars. Send for it today. Just address

American Eveready Works of National Carbon Co., Long Island City, New York

Meet the Demand

for this popular pump

Big Sales through big advertising and big demand

"Sure, old man, I've got a Yankee Pump in the car. That will do the work." You can always be sure of a tire pump that works by carrying a

YANKEE PUMP

90 Pounds Before You know It

You may have a power pump that is sometimes powerless —or a foot pump; but you need this powerful, full-lunged Yankee Pump because it's always sure, and easy to work. You stand up straight, pump with one hand, and the gauge tells you when it's "enuf." A woman can use it just as readily. It's "easy air." Ask your dealer to demonstrate a Yankee Pump to you today. If he hasn't one in stock, drop us a postal, and we will see that he gets one. Don't wait for the vexatious emergency.

BAILEY
NON-STALL
DIFFERENTIAL

A Fundamental Necessity For Every Car

The Bailey Non-Stall Differential is *not* an *accessory*. It is *not* an added convenience!

It corrects a basic weakness.

The old-style differential, in use since the first automobile, both fails to do what it should and does what it should not.

The Bailey allows the outside wheel to overrun when the car is going around the corner. In this respect *only*, it resembles other differentials.

The Bailey differs, in that it intelligently sends the power to the wheel which has traction and can use it.

Old-style differentials let the power go to waste by sending it to the wheel that does not have traction—(the wheel in the mud, for example).

This causes practically all skidding, slipping, stalling, spinning and side-swaying.

It is an enormous unnecessary waste of power and tires, and often causes accident troubles and expense.

The Bailey avoids all of this.

With the Bailey no power goes to waste, but *all* of it is used *properly*.

It makes you master of all road conditions.

Anybody can install it quickly.

It can be fitted to any rear axle.

Great Dealer Opportunity

Owners and dealers should write us for complete information.

Bailey Non-Stall Differential Corporation, Chicago, Illinois, 1124 Michigan Avenue

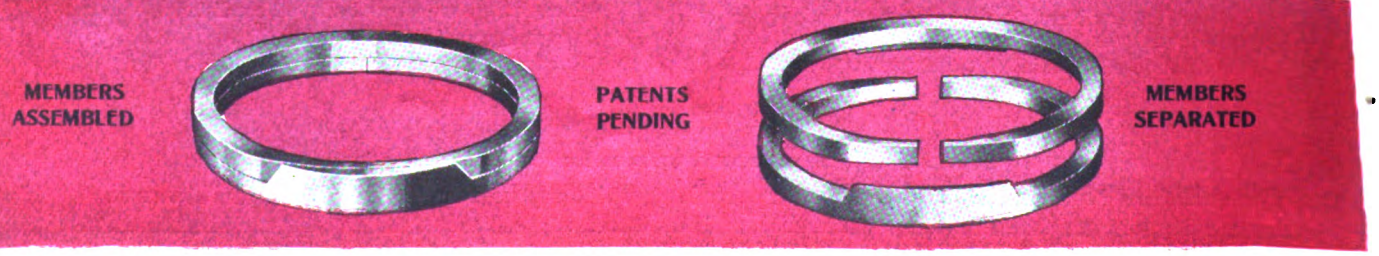
MORE POWER AT LESS COST

Here—at last—is the perfected piston ring—that actually does what others claim to do.

The double flange seal joint is guaranteed not to leak or score the cylinder, and gives a very high compression, which greatly increases the power of your engine—at less expense.

Jointless Piston Rings

Price $1 Each



The "Jointless" has been highly endorsed by automobile engineers and mechanical experts who know correct construction.

Write for circular which gives complete description, sizes, prices, etc.

Dealers and Garage Men

Dealers, Garage and Repair Shop Owners should immediately increase their stock of JOINTLESS Piston Rings to take care of the large demand. Order from Jobber now. Be ready for more business. The JOINTLESS will outperform any other piston ring, regardless of cost. To use them is to appreciate their absolute superiority. It is the logical ring to buy. If your jobber hasn't the JOINTLESS in stock, send your order direct to us. Liberal discount allowed.

Yours is the only starter we have ever seen that worked satisfactorily on a Ford car.

The above extract is a "composite" of expressions received from hundreds of satisfied purchasers of the

A·B·C STARTING & LIGHTING SYSTEM FOR FORD CARS

Dealers and Ford owners, the country over, are unanimous in voicing this testimony. The A. B. C. System is best for Ford cars because it is built on the only right principle. It is a strictly two-unit system. The dealer who handles it sells satisfaction. He can stand back of the A. B. C. without fear or hesitation. He will find that every A. B. C. sale is a standing advertisement of his knowledge and good judgment.

Six Things to Remember

For Your Customer.

1—That the A.B. C. System is strictly two-unit —as good as used on all the best cars.
2—That the A. B. C. System does not cut down the power and speed of the Ford; nor interfere in any way with the operation and accessibility of the Ford engine.
3—That the A. B. C. System distributes its weight equally on both sides of the car.

For Yourself.

1—That the A. B. C. System is easiest to sell because it has more talking points than any other Ford starter.
2—That the A. B. C. System is easiest to install because of the simplicity of design.
3—That the A. B. C. System requires minimum expenditure of time and labor for adjustments and repairs. You keep the profit.

Any one of these points is sufficient reason for the dealer to sell—for the Ford owner to buy—the A. B. C. in preference to any other starting and lighting system for Fords.

It will pay you to investigate—now—today—at flood-tide of the tremendous sale just starting. Our helpful policy—"ON AND OFF YOUR SHELVES"—will interest you—profit you. We've worked it out to a sales certainty.

ANY REASON WHY YOU CAN'T MAIL THIS COUPON—NOW?

A. B. C. Starter Co.

$250 in Gold for the Best Slogan

We need a good advertising SLOGAN for VULCAN Springs; and in order that you may successfully compete, we submit an outline of our policy and aspirations.

QUALITY

VULCAN Springs have and shall always carry the highest standard of quality—only the good endures.

SERVICE

VULCANS are today made in 588 different types, and in our five direct Branches we actually stock over 80,000 springs. Today, good assorted stocks are available in over 1,800 cities; and, in a few years, we propose to cover 8,000 cities, showing well chosen stocks with reliable dealers.

Rules of Contest

1. Contestant must be associated in some branch of the Automobile Industry, either as Dealer, Jobber, Repairer or Salesman of cars or accessories. Carriage and Wagon Makers and general Hardware and Sporting Goods trade not barred. Any employee of above concerns also eligible.

2. Slogan must be submitted on letterhead of above named trades, and no writing within two inches of slogan. Contestant's name and address must be plainly written below.

3. If several contestants submit the same slogan, in case of acceptance, the full amount will be given to each. Contest closes July 15th.

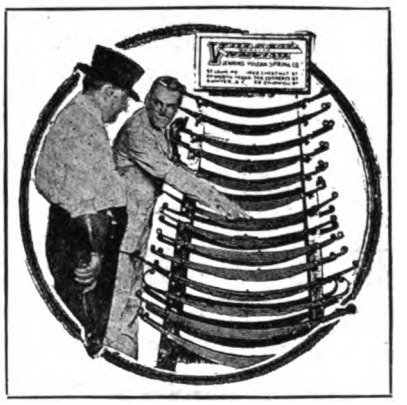
FIT

We assume the high salaried engineers who design cars nowadays are on their mettle to produce the best designs. In every case, our springs must be an exact duplicate of the spring intended to replace.

HONEST TRUTH

We confine our appeal to the merits of VULCAN Springs and it has always been and always shall be our endeavor to tell the absolute truth regarding the quality of our product and the extent of our service.

VULCAN Springs are as durable as the best grade of material and most careful workmanship can make them. We mention this because good intent is a valuable consideration in the making of a slogan.



JENKINS VULCAN SPRING CO.

TO SUM UP

VULCAN Springs must be immediately available to the man who needs one, and said man must be so impressed with the quality, fit and service, that he will come back for more. Our copyrighted trade mark shows on every spring. Liberal discount to the trade. Now cut this out and send us a good slogan.

For Your FORD

The PETRY CUT-OUT

Planned and constructed with the same thoroughness as the Petry Cut-out for high priced cars.
Quickly and easily applied and stays permanently **where in belongs.** Gas tight joints. Adjustable spring well away from all heat. No back pressure. No flutter to the valve. No strain in exhaust pipe. Gases are discharged **through** a flaring opening which intensifies sound, facilitating tuning up of motor.

Sold, complete with pedal and chain, for $3.50. Ask to see the Petry at your dealer's.

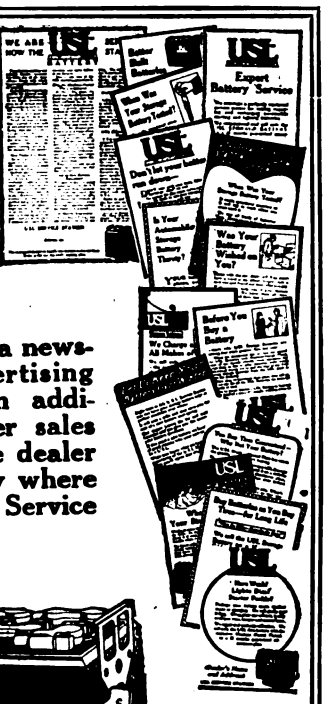
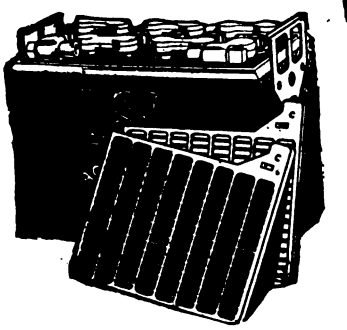
A New Record Established



USL leadership sets a new figure in the battery business.

The *quantity* of USL Batteries used in new cars exceeds any other make.



This statement is not based on the largest list of *names* of cars but on the greatest *number* of cars produced by automobile factories.

Our tests of last year proved to the makers of cars that USL Batteries with Machine-Pasted Plates were more durable than any old-style battery. We *proved* our case and the *orders* followed.

We have an agency proposition and a service station plan of interest to dealers who are looking *ahead.* If you are looking for a real money-making battery proposition—write us.

We conduct a newspaper advertising campaign in addition to other sales helps for the dealer in every city where we have a Service Station.

FIFTH EDITION—JUST OUT!

IMPROVED ONE HUNDRED PER CENT.

Dyke's Auto Encyclopedia.

SEVERAL BOOKS IN ONE.

ENTIRELY REWRITTEN AND ENLARGED—UP-TO-DATE

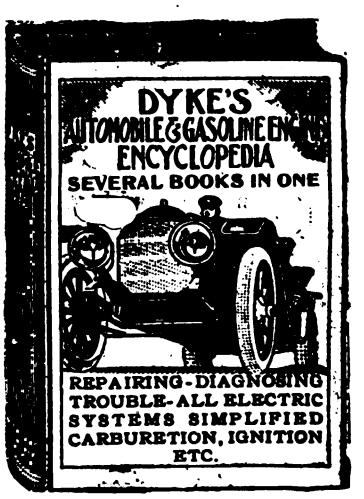
SOME FACTS CONCERNING THIS ENLARGED 5TH EDITION:

There are **50 Instructions.**
2370 Illustrations.
3 Supplements in addition to the 50 instructions, part printed in two colors, treating on the construction, operation, repairing and adjusting of the **FORD, PACKARD** and **KING EIGHT.**
824 pages, large size, 6¾x9¾ inches.
350 pages and **976** illustrations on **Electric Ignition, Electric Starters** and **Generators.**
34 pages and **75** illustrations on the **Delco system alone.**
74 pages and **254** illustrations on **Adjustments, Tests,** etc., of leading **Electric Systems.**
99 pages and **534** illustrations on **Repairing.**
29 pages and **180** illustrations on **Tires** and **Tire Repairing.**
44 pages and **97** illustrations on **Carburetion.**
84 pages and **239** illustrations on **Engines** and **Parts.**
21 pages on **Digest of Troubles.**
4000 lines to the **Index.** This is a feature worth noticing, as it means a ready reference on everything pertaining to motoring.
Index is printed on **colored** paper, easy to refer to.
Dictionary is also included, which gives the meaning of motoring terms.

You must see this new 5th Edition in order to appreciate just how complete a book it really is—Order N-O-W.

The Price is still **$3.00** (or **$3.32** postpaid).

How to Become an Expert Automobile Mechanician



The quickest and cheapest, but BEST way, is by studying Dyke's Automobile and Gasoline Engine Encyclopedia.

It is a practical, simplified instruction on everything you want to know and OUGHT to know about motoring.

First you learn the principle of construction of each and every part of a car and engine—then the variance of construction—then the adjustments and repairs.

You learn how to diagnose troubles in a scientific manner. Step by step you advance until you are a *real expert* on timing the valves and ignition, repairing and adjusting. You learn the carburetion subject so thoroughly, you can adjust any make.

You will like this book, in fact we will guarantee you would not sell it for three times its cost if you could not get another.

It's worth ten times its cost if only placed on the shelf and used as a reference.

Beware of Imitators—this is the *original, simplified* book on REPAIRING, ELECTRICAL SYSTEMS, TROUBLES, Etc. It is the only book in the world combining all these subjects under one cover. Why get three—or four books?

Mr. Dyke published the first practical Automobile Book in America.

SAFETY FIRST FOR WELDERS

B-B-B Diaphragm Safety Device

How often have you heard of a serious accident because of the poor design or weakness of a regulator? Because of the nature of oxy-acetylene welding and cutting it is of the utmost importance that the apparatus used be properly designed and made to insure the operator.

Accidents are Impossible

The B-B-B Diaphragm safety device takes care of any excess gas pressure—the safety device works like the blow-off on a steam boiler. The pressure never reaches the danger point. B-B-B regulators are strong, durable and reliable.

Welding and Cutting Torches

B-B-B welding and cutting torches are made with the same care and thought as are B-B-B regulators. They are built to give maximum results with perfect safety.

ALL YOUR GAIN

It Is a Hobby with Some Men to See How Good They Can Make a Thing

IN THIS CASE IT HAPPENS TO BE THE

TESTITE PISTON RING

And a very—VERY Good Ring It Is

Made with an eye single to absolute technical precision. You would hardly imagine it possible that such a supposedly common thing as a piston ring could be made so uncommonly good.

Testite Piston Rings are made in all sizes to fit all motors.

Testite Piston Rings save gas by utilizing the entire fuel charge in the production of power. There is no waste. No loss of power, no waste of exploded gases past piston ring openings.

Testite Piston Rings are a boon to marine, and also to aeroplane motors, where the highest compression is so vitally important.

Testite Piston Rings make your motor measure more power, make it more responsive, and though the highest in efficiency, are the lowest in price for piston rings of their character.

Every ring is inclosed in a separate envelope with directions for installation and are packed twelve in a box for the trade.

Our literature, we believe, treats the Piston Ring question in an intelligent manner—learn more—write us—today—that's better than forgetting it.

OWN AUTOS

They Are Physicians

64,000 Strong—*Over 50,000 Using Automobiles* in Their Practices

The medical profession offers to manufacturers of automobile accessories and supplies one of the most responsive markets.

The Automobile a Necessity

The automobile with the busy physician is a real necessity. He needs efficient means of transportation, which implies a moderate priced serviceable car and accessories of proven value and standard quality.

Physician a Frequent Buyer

The doctor's average mileage per year is 25,000 miles. He drives in all seasons, every day. In many cases his mileage is higher, according to the exigencies of his practice. From this fact, he is considered a frequent buyer.

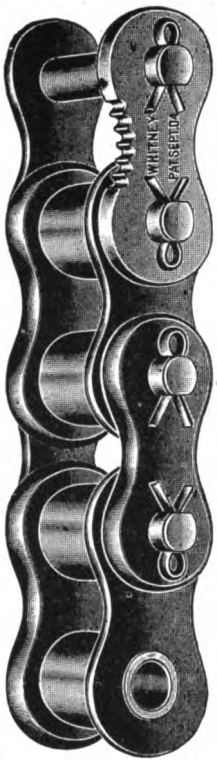
Professional Paper an Effective Medium

There is no better way to get **close** to the physician than to appeal to him through the advertising columns of his favorite professional paper.

Direct Returns and Dealer Help

For direct returns as well as **real** dealer help, THE JOURNAL can be of great value to any advertiser.

Physicians' Influence Valuable



Our 64,000 readers are in daily touch with over 32,000,000 people —1 physician to every 300—consider the extra advertising value to be gained from his recommendation of any product.

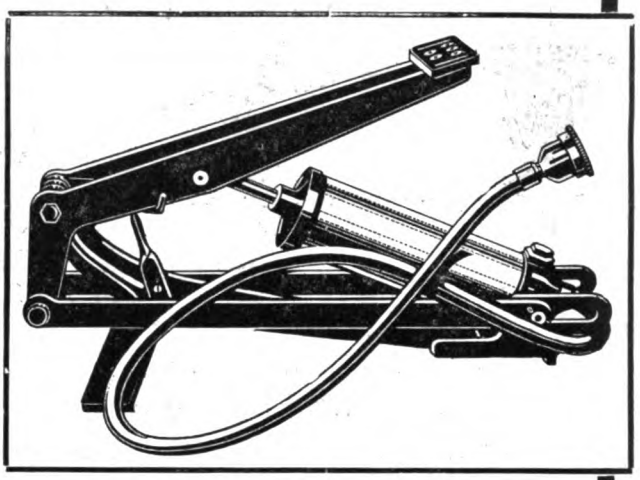
THE PETELER FOOT TIRE PUMP

REVOLUTIONIZES TIRE PUMPING

Every car owner in the country will give *buying* consideration to the Peteler Foot Tire Pump—because it revolutionizes the job of inflating tires.



Blisters on your hands, and a crick across your back accompany the longshoreman's job of pumping a tire with even the best of the hand pumps.

The Peteler does it by using your weight and a simple, easy leg motion; you do not bend up and down, you don't *handle* the pump, you don't finish the job wheezing like an old man with asthma. And you finish much *sooner.*

This pump will be the best seller in any line this year—simply to show it and demonstrate it makes a sale. It will sell in every locality to owners of any and every make of car.

The man with a hand pump *needs* it—the man with a motor-driven pump will *want* it when he sees how easily it works.

They'll both *buy* it when they find how efficient it is and note its splendid finish and stanch construction—and remember, *finish* and *substantial construction* are characteristics of every accessory we have ever offered.

The Peteler FOOT TIRE PUMP

SPECIALISTS IN FINE RADIATOR EMBLEMS AND ORNAMENTS

IT MAY BE YOUR TURN NEXT
TO MEET WITH AN ACCIDENT ON THE ROAD.

It may also be a case of life and death to have the materials at hand for prompt treatment. We have recently made arrangements for a First Aid Case for emergencies especially for the readers of the AUTOMOBILE DEALER AND REPAIRER.

This case is made of heavy Bessemer Steel, size 11½x5½ and 2¼ inches deep, finished in Black Baked Japan and fitted with a strong instantaneous snap. It is strong enough to resist injury to the contents through accident or dampness.

The contents have been carefully selected to supply the needs in an emergency, before the doctor comes. All gauze, bandages and cotton have been prepared in aseptic laboratories under the same rigid inspection as those supplied to the United States Army and Navy.

The contents of this case consists of:—1 "First Aid to the Injured" Instructions. 1 Yard plain Sterilized Gauze for dressing large wounds. 10 Yards 2-inch Sterilized Gauze Bandages for dressing cuts and bruises. 10 Yards 2½-inch Sterilized Guaze Bandages for dressing cuts and bruises. 1 Package Sterilized Absorbent Cotton for pads and dressings. 1 Box Carbolic Salve for burns, sores, insect bites, etc. 1 Yard 1 inch Zinc Oxide Adhesive Plaster for retaining dressings and covering small wounds. ¼ Ounce Tincture of Iodine, an antiseptic for immediate use on all wounds and abrasions. ¼ Ounce Spirits of Ammonia for use in case of shock, heart failure and faintness. ½ Dozen Safety Pins.

The retail price of this outfit is $2.50. We have made an arrangement with the manufacturers of such a liberal character that we can supply this outfit with a subscription to the AUTOMOBILE DEALER AND REPAIRER for a year, for the regular price of the outfit, $2.50.

In case you have already subscribed for this year, we will send you one of these outfits, postage prepaid, on receipt of $1.60, which may be remitted by check, money order, or in any convenient way.

Every subscriber to the AUTOMOBILE DEALER AND REPAIRER should have one of these outfits. It may mean the saving of your own life or the life of some friend. *ORDER AT ONCE AND THEN YOU WON'T FORGET ABOUT IT.*

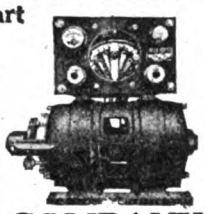
BATTERY CHARGING BRINGS BIG PROFITS

READ THIS STORY OF H B PROFITS

April 14, 1917.



Hobart Brothers Company, Troy, Ohio.

Gentlemen: You will be pleased to know that the HB Battery Charger we bought from you practically paid for itself the first month we used it. We charged 210 batteries at a cost of $18.00 and received 75 cents per battery from the owner. Our income was $157.50, with a net profit of $139.50. You have the most efficient, and the most satisfactory charging outfit for automobile storage batteries that we have ever found. Anyone in our place can operate it, as no electrical knowledge is necessary. We have never had a moment's trouble with our HB Charger and the customers are better pleased with their recharged batteries than ever before. This HB Charging outfit is one of the best investments we have ever made, because it costs so little to operate and the profits are so big. We only wish we had found out about it sooner. We can recommend your charger to all garage owners and battery men as superior in every respect. Yours very respectfully,

RSS/BCS REX BATTERY SERVICE STATION. Per B. C. Sorenson, Mgr.

The original of this letter is on file in our offices at Troy, Ohio.

You, Mr. Garage Owner, Can Start This Business for $15

as first payment for this money-maker, the balance in small monthly terms. Your profits each month should easily take care of these payments. You, too, will find an HB Charger the best investment you ever made. One to seven batteries charged at once. Average cost 15 cents, average price to motorist 75 cents to $1.50—profits about $4.50 per capacity run. ORDER NOW! You take no risk, as we want the HB Charger returned if unsatisfactory. That's only part of our guarantee. Tear out and mail this ad today, with your name, for full particulars.

LISTEN!

You Dealers and *Repairmen* Who Are Particular About The Quality Of The Goods You Sell

WHEN you sell a Harvey spring there are never any kicks or "comebacks," because Harvey springs give absolute satisfactior to the car owner. They have no bolt hole at center—no weak spots anywhere—and are guaranteed from end to end against all defects. If a spring proves defective at any point, we will replace it.

We are partners with every Harvey dealer. Not silent partners, either—we're spending thousands of dollars this year to post car owners in every section of the United States on the merits of Harvey springs—urging them to look for a Harvey dealer when in need of replacements.

It will pay you—big—to connect with this live-wire advertising. Let people know you handle Harvey springs if you expect to get your full share of spring replacement business—and profits.

Harvey springs are made for over 600 of the leading makes and models of cars and each spring is an exact duplicate of the spring it is intended to replace—fits with an accuracy that will surprise you. Write us at once for name of your nearest jobber.

PARKER-HYDRAULIC PRESSED STEEL WHEELS

FOR FORDS

Make an End of Wheel Troubles

Will Not Creak and Are Unbreakable

Patent No. 986,452

When a wooden wheel is broken, it usually is necessary to get a new wheel. When a Parker-Hydraulic Pressed Steel Wheel is bent, it can readily be straightened.

Parker-Hydraulic Pressed Steel Wheels weigh eight or ten pounds per wheel less than the ordinary wooden wheel with demountable rim.

Being made of steel, these wheels are more durable than wooden wheels and they have a baked-on enamel finish that will not crack or chip off like paint.

Tires can be changed in three minutes, due to the improved method of demounting the rims.

Price, per set, $32.00

F. O. B. Cleveland, Ohio

Your choice of either red or black spokes. Each set, neatly crated, includes four wheels and one spare rim, socket wrench and new hub bolts.

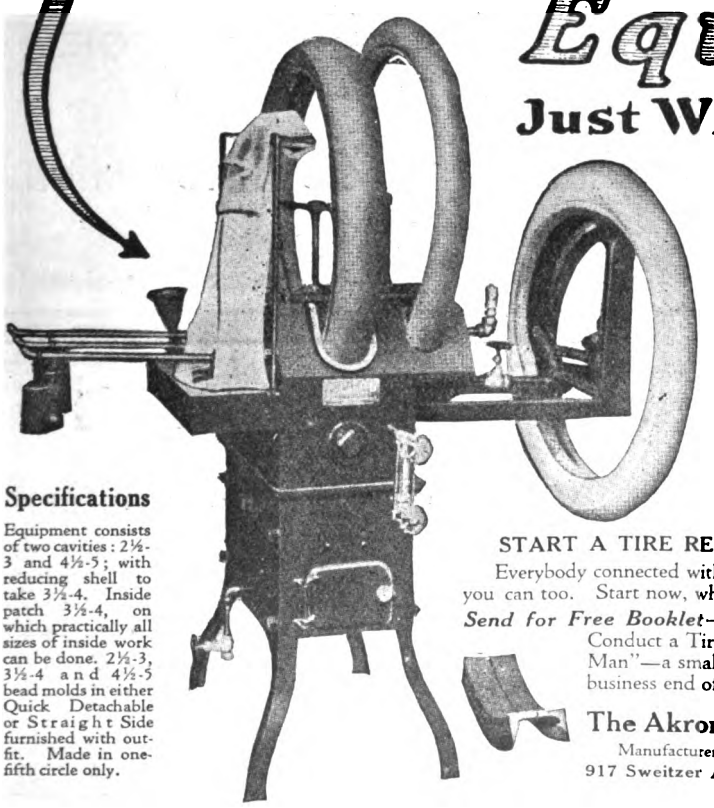
FORD OWNERS, STOP WASTING GASOLINE
Have an UP-TO-DATE $20.00 CARBURETOR for $2.00

The NEW YORK GASOLINE ECONOMIZER

is ATTACHED to and becomes a PART OF your present carburetor. It moves with the throttle and supplies oxygen from the air in such correct proportion to the throttle opening that more power is ACTUALLY DELIVERED FROM LESS GASOLINE.

This is NOT a new discovery. It is NOT an extensively advertised disappointment in the shape of a suction operated air valve screwed into the inlet pipe. *But* it is simply a cleverly devised ADDITION to YOUR present carburetor, the same as built into and found on all highly developed, expensive, present day carburetors. This is what we guarantee. Our device at $2.00 *will* make your carburetor the equal of any made, and will give you the GREATEST POSSIBLE GASOLINE ECONOMY.



You can attach it in 15 minutes, without machine work. As no holes are bored in the inlet pipe, trial can be made without damage, and your $2.00 will be returned without argument, upon receipt of Economizer within 30 days after purchase date.

THIS Great New Equipment

Just What Tire Repairmen Want

TYPE "F"

BIG CAPACITY VULCANIZER

SELF-CONTAINED OUTFIT

Only $125

One of the greatest achievements in the building of tire repair equipment. Look at the illustration; read the specifications on the side. A big capacity vulcanizer that will take the wide range of work that this equipment does, so that you can make almost any kind of repair on both inner tubes and outer casings of practically any size or make—with a self-contained source of steam supply so that you do not need to buy a separate steam boiler or generator—and having the high quality and specifications of this one, has never been offered before for $125.

We make a complete line of Tire Repair Equipment and are in a position to furnish outfits to meet various requirements of service, output and adaptability, at prices ranging from $50 to $225. If interested, ask us for complete catalog.

Specifications

Equipment consists of two cavities: 2½-3 and 4½-5; with reducing shell to take 3¼-4. Inside patch 3½-4, on which practically all sizes of inside work can be done. 2½-3, 3½-4 and 4½-5 bead molds in either Quick Detachable or Straight Side furnished with outfit. Made in one-fifth circle only.

START A TIRE REPAIR BUSINESS—MAKE BIG MONEY

Everybody connected with the automobile business is making big money—you can too. Start now, while the best locations are still available.

Send for Free Booklet—Write today for free booklet, "How I Would Conduct a Tire Repair Business—By an Old Tire Repair Man"—a small booklet, but a very practical one on the business end of the tire repair business.

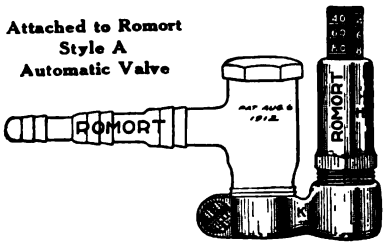
Attention, Mr. Garageman!

ROMORT TIRE TESTER ATTACHMENT

PRICE, $1.50

This is a device for attaching your gauge to Romort Automatic Air Valve, and gives the service station a permanent holder for its gauge, ready for instant use by the public, eliminating the necessity of loaning gauge to operator, who three times out of five will drive off with your gauge in his pocket.



Simply screw your gauge into this holder and you have a tire tester and tire inflator combined in one, and the old trouble of losing gauge is forever over.

Every garage with free air should be equipped with the Romort Automatic Air Valve and Tire Tester Attachment.

The above price includes the Attachment only.

CAUTION—When ordering, state whether for Style A or B Valve.

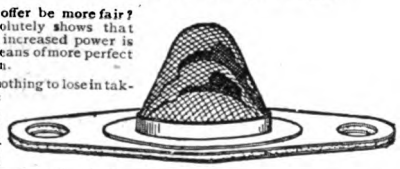
GASCO
GASOLENE ECONOMIZER



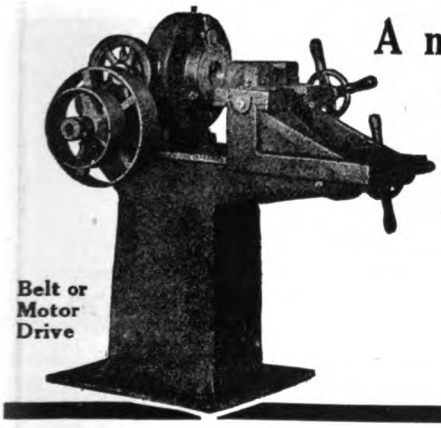
NOW—IT'S UP TO YOU!

Truth is never crushed to earth if given a square deal. Pin a dollar bill to your letterhead—mail it to us and prove Gasco's distinguishing traits.

First, determine the speed of your motor while idling and with the throttle all the way down.

Then unbolt the carburetor flange from the intake manifold and insert the Gasco as if it were a gasket, tighten up the bolts and start up the motor.

If the motor doesn't run faster than it did before, just send the Gasco back and we'll refund your money.



Can any offer be more fair? This test absolutely shows that with a Gasco increased power is obtained by means of more perfect fuel combustion.

You have nothing to lose in taking advantage of this offer, and you can readily prove for yourself that Gasco will save its cost in a short time in the saving of fuel, besides adding power, reducing carbon, and preventing fire due to backfire.

Thousands sold—one large concern purchased 3200.

Dealers everywhere find it a quick seller and a good profit-producer. Our sales plan calls for a small investment and gives a quick turnover. Write today for particulars.

CUTS CONTINUALLY AT THE VITALS OF YOUR CAR

Under the magnifying glass the smoothest piece of metal looks like a jag toothed saw. These unseen teeth are at work every minute your car is in motion. They are wearing out and destroying the surfaces of gears and bearings.

A perfect lubricant works in between the metal surfaces, separating them, and allowing them to travel on the lubricant, wearing it out, instead of the metal. As a lubricant approaches perfection, the amount of wear on metals becomes practically nothing.

After hundreds of miles of travel, metal surfaces show only an oil polish when NON-FLUID OIL is used.

At every point where metal-to-metal contact sets up friction, NON-FLUID OIL will insert a slippery, adhesive lubricant film, which stays in place regardless of temperature or pressure, and puts a stop to destructive wear.

The consistent use of NON-FLUID OIL will insure long life for your car at least expense for repairs. Yet NON-FLUID costs no more than common grease, which it outlasts three times.

"K-00 Special" grade is for gears; "K-000" is for bearings. Your dealer has them—packed only in orange-colored cans.

THE RED ROAD BOOK

250 Pages. Price, $2.00

—and—

THE AUTOMOBILE DEALER AND REPAIRER

$1.00 a Year

BOTH FOR $2.00

A great many of our subscribers will be glad to know that we have made arrangements with the Bullard Co., of Boston, publishers of the "RED ROAD BOOK," on such favorable terms that we can offer this admirably arranged book, size 9¾ x 9¾, and comprising 250 pages, in connection with the Automobile Dealer and Repairer for a year, for $2.00, which is the regular retail price of the book.

In other words, by subscribing to the AUTOMOBILE DEALER AND REPAIRER, the subscription rate of which is $1.00 a year, you get the "RED ROAD BOOK" AT HALF PRICE.

We don't know of any better book than this on the market. It is bound in flexible cloth, and comprises road maps of the following states:

All of the New England States	Pennsylvania	Virginia
New York	Maryland	West Virginia
New Jersey	Delaware	District of Columbia

These states are largely patronized in the Summer by tourists from all over the country, who like to visit the Catskills, the Adirondacks, and the White Mountains. The "RED ROAD BOOK" also gives maps of that portion of Canada reached by routes from Northern New York, Northern New England and Northern Maine.

It further gives 153 city street maps, to which are added road distance tables, ferry tables, and the necessary population and location indices for all towns.

Reading route matter in connection with the principal routes is tersely told, and will be printed in black, and their reverse routes printed in red, to avoid confusion.

The aim in the production of this work is simplicity. Too many automobile route publications attempt so much, that in their efforts to be "complete" they become "confusing." The publishers of this work say that many years of motor travel and the observations of others lead them to the opinion that once out of the confusion of a city's streets, on the broad highway, the need is less for the detailed, must-be-closely followed printed words, comments and instructions of the path itself, but rather the need is for the accurate knowledge that the road to town A and thence to town B is of "automobile goodness," and that it proceeds via this and that village, this or that side of a lake or a mountain, with crossing railroads, or paralleling trolley lines, as a check on location.

Thus is one free to carry out his original purpose; namely, to see the country, with this instruction book.

If with such maps as are shown in this road book, one sees that they are to pass within a few miles of a well-known and picturesque lake, or historic hamlet, or perhaps desire to go "across country," a good road map is the best aid for this free lance mode of travel.

A new edition of this road book is now being prepared, and will be corrected right down to date, and will contain much new material. The book will be ready for delivery from the first to the fifteenth of April.

All orders sent to us will have prompt attention just as soon as the book is issued. In case you have already renewed your subscription, a Red Road Book will be sent on receipt of One Dollar Address:

"NORMA"
BALL BEARINGS
(PATENTED)

Dependability—isn't that the really essential quality in any car? Isn't dependability—so far as car performance is concerned, synonymous with pleasure-capacity and service-capacity? And doesn't dependability in the car as a whole demand dependability in every detail of construction and equipment? The ignition apparatus and lighting generator, for instance?

"NORMA" Bearings are the standard bearings in the high-grade magnetos and lighting generators used on cars and trucks of the better class, and adopted because of their proved dependability. It is, then, a mere statement of fact to say that "NORMA" Bearings identify dependable magnetos and lighting generators.

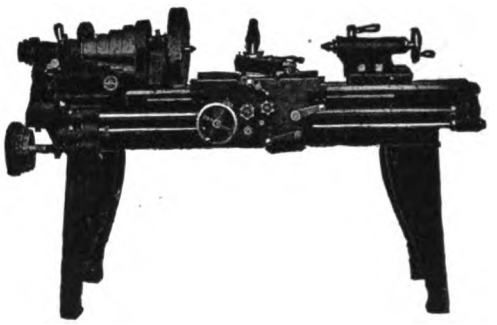
An Absolute Necessity For Ford Cars

THE HANDY

Horn Push Button and Holder



THE Horn push button on the FORD is located in a decidedly awkward place—on the steering column. To reach it one must put the arm either through or around the wheel. It's not only unhandy – it's unsafe. The HANDY horn push button and holder is placed where it rightfully belongs—on top of the steering column in the center of the steering wheel.

Every FORD owner wants this necessity as soon as he sees it. When he gets it he'll be proud of it. He cannot afford to be without it.

Come complete and can be attached in five minutes.

"YANKEE" Breast Drill No.1555

For-Hard-To-Get-At-Places

Garage men and other mechanics who have intricate jobs where every minute counts, appreciate the possibilities of a tool like this "Yankee" Breast Drill.

With the five ratchet adjustments, a man can do a job of drilling in places impossible for any other breast drill without taking the job apart.

Five adjustments controlled by Ratchet Shifter in center of barrel—1st notch, Plain Drill; 2nd, Left Hand Ratchet; 3rd, Right Hand; 4th, Double Ratchet where the drill cuts with every movement forward or backward of crank even through a short arc of two inches; 5th, Gears locked for changing drills.

"YANKEE" Ratchet Breast Drill

TWO SPEEDS

No. 555—Two jaw chuck
No. 1555—Three jaw chuck **Price $7.70**

"YANKEE" Ratchet Hand Drills Nos. 545 and 1545—two and three jaw chucks. Double speed; same ratchet movements as one illustrated, made lighter, with polished hardwood handle. Price $6.80. "YANKEE" Plain Breast Drills Nos. 455 and 1455—two and three jaw chucks. Double speed, but *without* ratchet movements, price $5.00, useful to garage men and auto owners.

"YANKEE" TOOLS *Make Better Mechanics*

PIERCE Governors

For Ford Cars

Owners of Ford trucks, delivery wagons and taxicabs, are learning from experience that fast driving is directly responsible for nearly all of the accidents, and for at least 75 per cent of the repair bills.

A Pierce Governor, through its automatic and positive control of the vehicle speed, eliminates both damage suits and repair bills, reduces gas and oil consumption, saves tires and springs, and prevents troubles that put cars in the repair shop.

It supplies just the right amount of gas to the motor, permitting the driver to get full power at all speeds up to the danger point, and gradually shuts off the power when that point has been reached. Can be set for any speed.

A Harvest for Dealers

Some dealer in your city is going to make a lot of money this year selling Pierce Governors. Are you the man?

Write for our proposition You'll find it interesting.

Builders of the All-Geared Drill

Try at Our Expense this wonderful Repair Outfit

Weight 90 lbs. boxed

Stewart Handy Worker "SIX-IN-ONE" Price Complete $14

Handiest combination of tools you ever saw. Just the thing for the garage, public or private. Wonderful value for the money. If you were to buy separately all of the tools you get with this outfit, and get tools of the same high quality, strength and durability, THEY WOULD COST YOU AT LEAST $25.

A COMPLETE, COMPACT WORK-SHOP

A strong, practical anvil; powerful vise up to 4½ inches, width of jaw 4 inches; a sure-grip steel pipe vise, takes up to 1½ in. pipe; A Corundum grinding wheel 5 inches by 1 inch; a two-speed drill press with 2 drills; a metal cutting wedge and driving mechanism of three speeds—direct, 4 to 1 and 16 to 1—easily regulated by changing handle grip. It operates grinding wheel, buffing wheel, and many other similar tools.

With the STEWART HANDY WORKER you can do car repairing, blacksmith work, home repairing, make plumbing repairs, keep knives and other tools sharp and in good working condition.

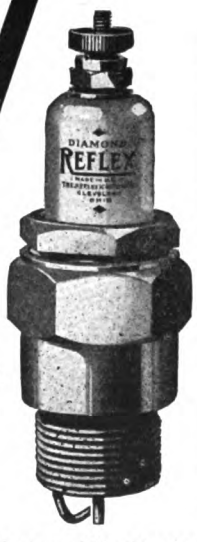
OUR SPECIAL TRIAL OFFER

Send for one of these great combination outfits today. Order with this understanding: If you aren't thoroughly satisfied in every way, you can ship it back and we will return every cent you paid out. THOUSANDS HAVE BEEN SENT OUT ON THIS BASIS AND NOT ONE HAS BEEN RETURNED.

Send only $2 with your order, and pay the balance when it arrives. BOOKLET GLADLY MAILED ON REQUEST. But the best way to appreciate this wonderful outfit is to order it, on our special trial offer.

CHICAGO FLEXIBLE SHAFT CO., 320 N. La Salle St., CHICAGO, ILL.

REFLEX SPARK PLUGS



Act as a "Magnet" for Dealers because one sale draws the car-owner back for a full set. Reflex plugs meet the demand for better spark plug service than comes with the car. They're built to stand up under the severest punishment because they're made with the strongest heat-resisting insulator known—Cromite Porcelain.

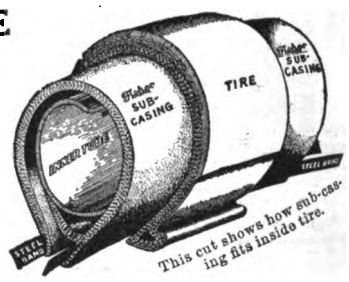
THE Fisher PATENTED "RIM-GRIP" SUB-CASING

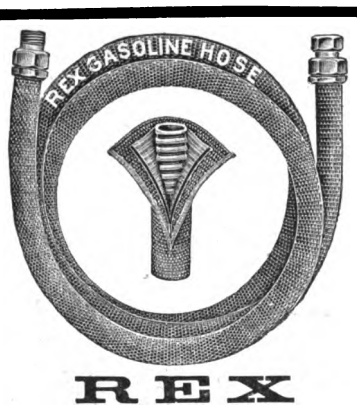
MORE MILES PER TIRE LESS TIRES TO BUY

THE BLOWS THAT YOUR TIRES RECEIVE, WHEN YOU STRIKE OBJECTS IN THE ROAD, LEAVE WEAKENED PLACES IN THE FABRIC.



A TIRE IS AS STRONG AS ITS WEAKEST PLACE

These weakened places are hard to detect now, but will result in blow-outs later.



RIM-GRIP SUB-CASINGS reinforce the fabric of the tire at all points from bead to bead. They make a partially worn tire stronger than it ever was. It can be worn out completely and the sub-casing used in another tire. As the cost of equipping a car with new tires is much greater than last year, it will pay you to investigate Rim-Grip Sub-Casings. *Write for particulars.*

FISHER MANUFACTURING CO.

1706 PAYNE AVENUE, :: :: CLEVELAND, OHIO

This cut shows how sub-casing fits inside tire.

THE FIRST 2 BOOKS OF THEIR KIND IN THE WORLD

A Complete Automobile Business Education for $3.50

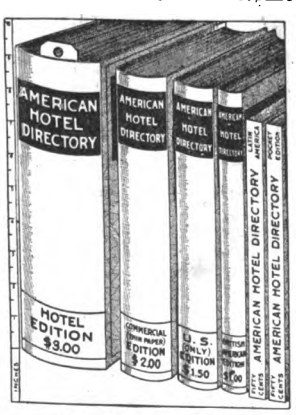
AUTOMOBILE BUSINESS

By J. H. NEWMARK

The first book in the world that discusses the automobile business from a money making standpoint. Every feature of it is thoroughly discussed from a dealer's view—opportunities that the industry presents today; best auto selling territories; organization; sales; advertising; promotion work; garage; service; accounting systems; and all other departments. 201 pages. Price $2.00 postpaid.

AUTOMOBILE SALESMANSHIP

By J. H. NEWMARK



A complete manual for the man desiring to sell automobiles; how a self propelled vehicle operates; simple definitions a salesman should know; manufacturing procedure in motor car factories—essentials of successful salesmanship; how to secure prospects; selling a car; steps necessary; what constitutes beauty, style, comfort, easy riding, convenience, power, flexibility; economy, durability, safety; how to interest prospects; demonstrations; securing order; woman in the case; trading problem; electric vehicles; trucks; etc. 121 pages. Price $1.50 postpaid.

Address all orders for the above books to

THE MOTOR VEHICLE PUBLISHING CO.

71-73 Murray Street, New York.

THIS YEAR'S AMERICAN HOTEL DIRECTORY

YOU CANNOT ASK US A QUESTION ABOUT ANY CITY AND HOTEL OF THE WESTERN HEMISPHERE THAT WE CANNOT INSTANTLY ANSWER. WE WANT TO ASSIST YOU IN PLANNING YOUR ITINERARY OR ROUTING YOUR TRAVELING REPRESENTATIVES. LET ONE OF US BE YOUR PRIVATE BUREAU OF INFORMATION.

HOTEL EDITION, $3.00—That's the big brother, he knows as much as all the rest of the family put together. He is built for heavy work and rough usage at big hotels. He's informed on everything but the time table on North and South America, from Bermuda to Hawaii inclusive.

COMMERCIAL EDITION, $2.00—Knows just as much as his big brother, but not so strong, designed for smaller hotels and commercial offices, where he won't have to work so hard, still, with reasonable, careful use, he's long lived.

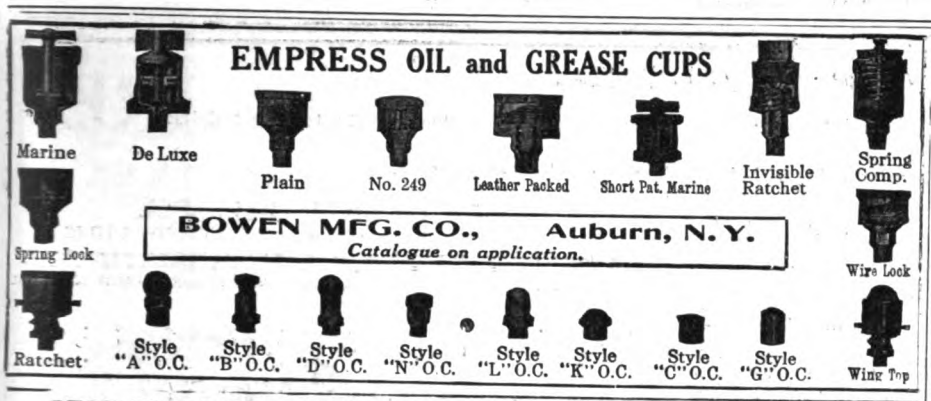
UNITED STATES EDITION, $1.50—A fine investment for any one who doesn't go outside of the United States, but when it is within these borders, you can't stump him with a reasonable question.

BRITISH AMERICAN EDITION, $1.00—This chap has completed a tour of all Canada, and the British American Islands, he knows all about those parts and the hotels.

LATIN-AMERICAN EDITION, 50c.—A little fellow to be sure, but still full of information about everywhere and everything fit for a white traveler to go or see in the Southland—from El Paso to Cape Horn.

POCKET EDITION, 50c.—The little book with the big circulation, designed for the traveler and his hand bag or coat pocket. Lists the principal cities, principal hotels, and points of interest in United States and Canada only.

All illustrated, printed on strong paper and cloth bound.



Either of the editions referred to above will be sent to any address on receipt of price. We would particularly recommend the **Pocket Edition** at 50 cents, as it will answer for the most part all practical purposes. Postage stamps accepted in payment. Address:

MOTOR VEHICLE PUBLISHING CO., 71-73 Murray Street, New York.

EMPRESS OIL and GREASE CUPS

BOWEN MFG. CO., Auburn, N. Y.
Catalogue on application.

STOP THE SPRING BREAKAGE.

It's a poor policy to risk repeating the annoyance of a broken or weak spring—and the delay—by saving only a very little in buying or selling a *cheaper* spring instead of a "NEW ERA *BETTER* SPRING."

Don't replace a broken spring with one no better.

Wise dealers—sell only the best—

New Era "BETTER" Springs are the oldest and largest used line for replacement—at same price as from car factories. Made for all cars, GUARANTEED one year against breakage or sagging, graphited between leaves for two years' lubrication.

Write for complete line, discounts—or state requirements and class of business.

NEW ERA SPRING & SPECIALTY CO.,
871 Woodward Ave., Detroit, Michigan.

SANBORN'S
Spindle Arm Silencer
FOR FORD CARS
Patented Aug. 31, 1915

One of the best things ever invented for the Ford. Absolutely stops all rattle in the arm, prevents wear and helps in the steering. Easy to put in by using a pair of nippers. No bolts to take out and not over five minutes time required. Insert from front side. Take hold of spring about half way from end, press ends together and push into place. Once there they will stay and you will have no more rattle from arm. Thousands now in use. Ask your Garage man for them. If he does not have them, send 35 cents and we will send a pair post paid. *Send for Price List.*

J. W. SANBORN MFG. CO., Hampstead, N. H.

Add $250.00 A MONTH EXTRA To Your Business

REPAIR AUTOMOBILE TIRES

Sounds like a whole lot of money to clear extra every month. Seems almost impossible, but that is what hundreds of men are doing who have added a Tire Repair Department to their business. **The investment is small, the profit large** and **returns quick and all cash,** besides the demand for tire repairing and retreading is constantly growing. Your garage is by no means complete, your business is not as profitable as it can be until you get in on the Tire Repairing and Vulcanizing end.

THE HAYWOOD TIRE REPAIR EQUIPMENT

Answers all the requirements to successfully handle this end of the business. With it and a little business judgment, success is certain. Every year adds thousands of new auto owners. They are looking more and more to economical tire service. The day of discarded tires is over, the Haywood Equipment makes this possible.

HERE IS YOUR OPPORTUNITY

Either as a side line to your present automobile business or as a business by itself, the Haywood Equipment will make money for you. **Tires go wrong all the time.** You know that. Keep them in tune. Give your customers complete service—repair their tires and all. This builds business and makes you rich. Experience unnecessary. You can learn easy—or teach a boy to handle this end. Be the boss and make the money. Learn the details now. Investigate. Act quick. Be the first. Send name and address only. A postal will do.

HAYWOOD TIRE & EQUIPMENT CO.
965 Capitol Ave., Indianapolis, Ind.

NO CARBON
(NO WASTE OIL)
MORE POWER
(PERFECT SEAL)
LESS FUEL
(OIL CONTROL)

A DOLLAR SAVED IS A DOLLAR MADE

Makes your engine run like new all the time.

LISTEN!

See that groove controlling the oil?

The oil in the groove forms a dam, gas cannot escape, oil cannot get past. That's why more power, no carbon, no gasoline or coal oil in the oil pit, injuring lubrication.

ISN'T THAT A REASON?

Write for booklet A2. Ford size or under 50c. Discount to the trade.

FAIR LIST PRICES FAIR TREATMENT

GOODRICH TRADE MARK TIRES

Start Your Customers Right With

GOODRICH Tubes

A TIRE is no better *than the tube* in it. For after all a *shoe* is but an armor to *protect* the vital part within it—the *tube* that holds the LIFE BREATH of the tire.

It is the duty of dealers to fix this fact in the minds of their customers together with the intense importance of getting the *best tube* to be had.

To help you determine the best tube, we ask you to take in your fingers a GOODRICH BROWN TUBE, and compare it with any other tube.

The very feel of it—its texture, its elasticity, as flexible as a big rubber band for all its tough thickness—tells you the striking difference.

Goodrich Brown Tubes cost more than other tubes, but a dealer should impress upon a customer that *cheapness* in a tube at the *beginning* means *costliness* in the *end*.

Goodrich also has an excellent standard tube at a lower price—THE GRAY TUBE.

Assure your trade that Goodrich tubes—another triumph of Goodrich's forty-eight years experience in rubber compounding—are the best "tubes for him in any case."

The B. F. Goodrich Company

AKRON, OHIO

The Piston Ring that Stands on Its Record---Not on a Promise

Do you realize how many piston rings are being sold on promises? It's put up to the owner to find out what they're actually good for after he's had them installed. That's a poor basis to build your business on.

What you want to handle and recommend to your customers is the piston ring with a successful record behind it —that you ***know*** will give satisfaction. That can only mean

McQUAY-NORRIS LEAK-PROOF PISTON RINGS

Their claims are based on what they've ***done.*** On the results of long, hard tests in every line of motor service for years.

That's the way you want to do business. And, in addition, remember, that you can get McQuay-Norris LEAK-PROOF Piston Rings in every size and over-size. You can give the prompt service that every owner is calling for.

Send for This Booklet—FREE

If you haven't already got "To Have and To Hold Power" —send for it. Every garage and repair man should read it. It will help your business. Write Dep't R.

A Tire Lesson from Europe

European Motorists Get 5,000 Miles *More* Service Out of Their Worn Tires

The European War

has taught us a tire lesson.

To meet the demands of economy behind the battle lines of Europe, engineers have made discoveries that should save American motorists thousands of dollars in tire bills.

Tires that have been discarded after only 3,000 to 5,000 miles of wear, can be made to render at least 5,000 miles more service.

England, France and Germany, Austria and Russia—all the fighting nations—have solved the tire problem in exactly the same way; solved it so that they now get at least twice as much mileage out of their tires, few punctures, non-skid service equal to chains, and an enormous saving in money. They did this by using steel studded treads.

Get 5,000 Miles More

You can get at least 5,000 miles **more** service out of the tires you have been throwing away or giving to the junkman for a few cents after you have driven them only 3,000 to 5,000 miles of service.

Over half the car owners in Europe are doing this by applying steel studded treads to their worn tires, and more than 50,000 American motorists have already taken advantage of this opportunity to save from $50.00 to $200.00 a year in tire expense.

Steel studded treads are a perfected product of the world's war. Take a look at the photograph above showing how the military cars at the front are steel treaded. This new tread has proven its value to the satisfaction of military engineers and to thousands of investigating European and American motorists.

It offers you the same economy and security. You are entitled to these advantages and we stand ready to show you at our **expense**.

Guaranteed 5,000 Miles Without Puncture

Durable guarantee

Treads are backed in writing by our signed for 5,000 miles of wear without a puncture. This guarantee holds good whether your tires are new or old. Think of it—to be able to drive your car without the constant nerve racking dread of tire trouble—it really means a **5,000-mile tire vacation!**

We Deliver Free

Without a cent deposit, we prepay express and allow you to decide. Remember the new Durable Treads—the only tire protectors in America built according to the foreign pattern—are gripped by the rim, just the same as the tire—absolutely water and sand proof—and are **applied in your own garage** in a few minutes time.

Special Discount

To motorists in territory where Durable Treads have not as yet been introduced, we offer a special discount on the first shipment **direct from the factory.**

Will you let us show you at our expense and risk? All we ask is your request for information—the coupon below is for your convenience.

Mail the Coupon

Tear it off and mail it **now**—don't run your tires "bare-footed" another week. We have an interesting book—"10,000 Miles On One Set of Tires," sample and copy of guarantee, ready to send to you FREE.

Stop throwing away your worn tires. Let us show you how to get 5,000 miles **more service** out of them, just as thousands of other motorists are doing.

Mail the coupon TODAY—do it now—before you turn the page and forget. You will hear from us within a week.

A Letter of Interest To You

EVERY man who owns a car or a motor boat should read this letter from the C. C. Smith Boat and Engine Company, builders of the fastest boat in the world—the Miss Minneapolis, which has a record of 63.57 miles per hour.

Proper lubrication of the high speed motors used in automobiles and in many boats is of paramount importance to the owners. Your experience has probably shown you that such lubrication may not in all cases be easily obtained.

TEXACO MOTOR OIL

in the opinion of experts who have studied the question of lubrication from every angle, does lubricate properly under even the most exacting circumstances.

The selection of this oil by Mr. Smith and his associated engineers should interest you, not essentially because it related to the fastest boat ever built and helped to give her her speed, but because to a certain extent their business prestige was at stake, and because they had at their disposal all brands of motor oil with which they could experiment and from which to make their choice.

Such impartial opinion from men of great experience in their field is worth profiting by. You can't do better than follow their example.

Use Texaco Motor Oil in your automobile or motor boat. The safest way, the best way, to buy it is in one or five gallon cans.

THE TEXAS COMPANY
New York Chicago Houston
DISTRIBUTING OFFICES IN MOST CITIES

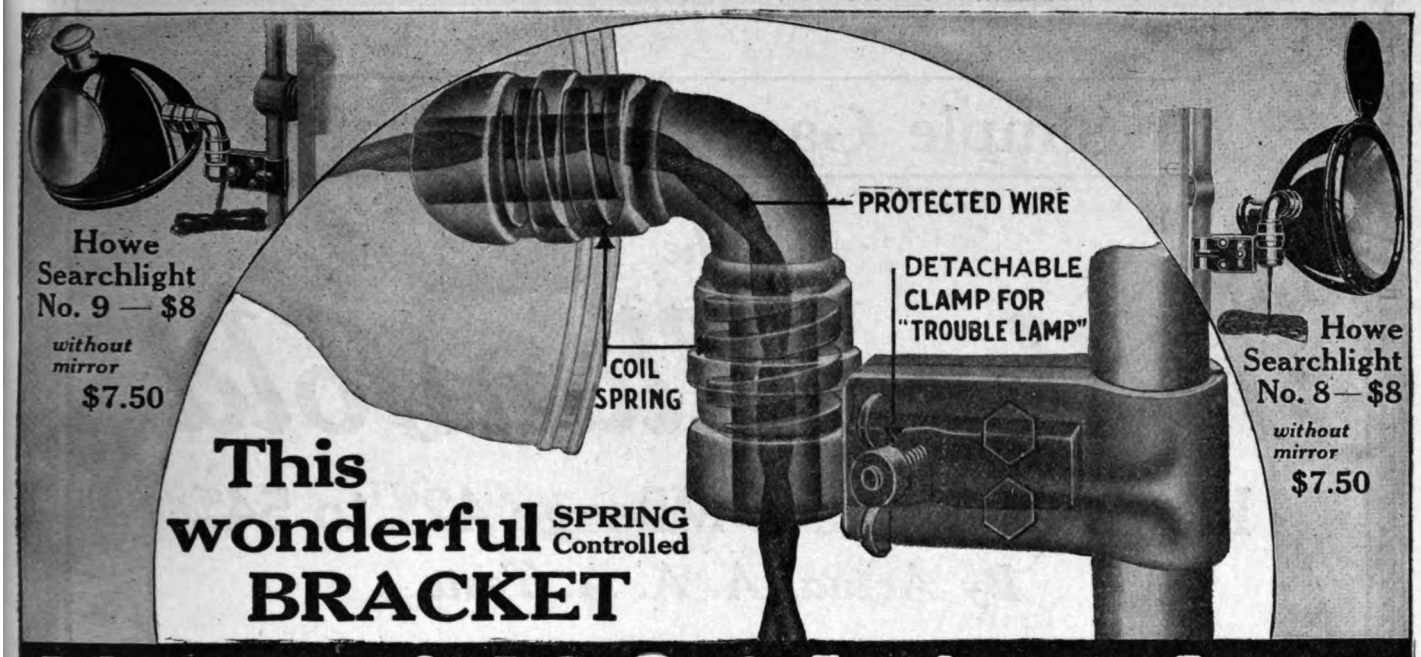
THE BOAT BUILDERS
C. C. SMITH BOAT AND ENGINE COMPANY
C. C. SMITH, PRES.

ALGONAC, MICHIGAN. Aug. 21,

Texas Oil Company,
Chicago, Ill.

Gentlemen:-

Enclosed please find check for ($15.90) to pay for our last shipment of extra heavy TEXACO oil. We herewith want to order for immediate shipment by Adams express 40 gallons in 5 gallon cans of TEXACO #556 extra heavy. We would also say to you that since the races in Peoria in 1914 we have used your TEXACO oil in the Baby Speed Demon, Baby Reliance, Buffalo Inquiry, Miss Detroit and Miss Minneapolis and up to the present time have never had to remove a bearing on account of lubrication or for the inefficiency of the oil. This may be of some value to you as an advertisement.



Please give this order your prompt attention we want this oil to drive next Saturday in the Gold Cup races.

Very truly yours,

C. C. SMITH BOAT & ENGINE CO.

Means Light Quick-Anywhere

THE *bracket* is what makes any spotlight worth while. The Howe has the *one* bracket that is 100% effective. You turn *directly* to the spot you want to see, as naturally and easily as you point your finger. Both joints of the Howe Universal Joint Bracket move at the same time. You operate it readily with one hand, yet *right where* you turn it, it STAYS—until again moved. Won't loosen from jars and vibration, for the turning joints are held under firm pressure by *two coil springs.* Through months and seasons of service, the Howe does not get weak or wobbly. *Just as we told you—the*

HOWE Searchlight

Is the Spotlight that car owners want.

They know that it is the bracket that makes the Spotlight worth while. They know from reading our advertising that the Howe Universal Joint Bracket is the one and only bracket that is 100% effective.

The demand is big right now. To get some Howe Spotlights quick, wire for a dozen, mentioning jobber's name.

The Howe is a good selling proposition all the way through—incomparable Spotlight—free display stand—live advertising co-operation. Send the coupon. Handsome display stand given free with initial order of one dozen.

For These Reasons The *Howe Leads Them All*

1—The Wonderful "Spring-Controlled" Bracket.
2—The Universal Joint permitting direct-turn to any angle.
3—Always "stays put"—never loosens or flops around.
4—Never sticks—never hard to turn.
5—Handy on-and-off switch in knob. Works easy while turning lamp.
6—Reflector gives perfect spotlight at all distances.

Six Other Reasons That *Put Howe Far Ahead*

7—A special clamp to fit each different style of windshield post; round, square, oval.
8—Hollow bracket protects wire. Prevents wear, short circuits.
9—Detached for trouble lamp by loosening one set screw.
10—Light weight—perfect streamline body—finish equal to your car.
11—National Mazda Nitrogen gas filled 21 candle-power bulb.
2—100% light efficiency without danger of glare.

A Simple Gasoline Problem:—

If the

Wilmo Manifold

Increases Gasoline Mileage 42% to 54%

By Actual A. A. A. Tests

How Much Gasoline Money Does the User Save With Gasoline at 25c a Gallon?

Ask every customer that question and see his immediate interest in the Wilmo Manifold, the great conservor of gasoline.

We can show letters from users testifying to as high as 80% increased gasoline efficiency—but the official A. A. A. tests showing 42% to 54% increase should satisfy anybody.

Wilmo Manifold sales are up in the hundred thousands—all in six months.

Made for many makes of cars. See the list below.

Help your customers cut gasoline cost and rid their engines of carbon the Wilmo way. Write today for interesting dealer information on this year 'round success.

The Whittier Company
227 First National Bank Building **Chicago**

How It Does It

The Wilmo Manifold is a one-piece casting, forming a combination exhaust and intake manifold with a thin dividing wall between. The heat from the exhaust brings the walls of the intake up to the proper temperature to fully vaporize the gasoline before it enters the cylinder.

The Wilmo Manifold vaporizes every atom of gas right at the valve openings. Leaves no wet gas accumulating on the walls of the intake passage. Makes a four-cylinder as flexible as a six. Permits you to drive slower or faster, and all with much less gasoline consumption. Makes an old motor and carburetor work without loading up on gas.

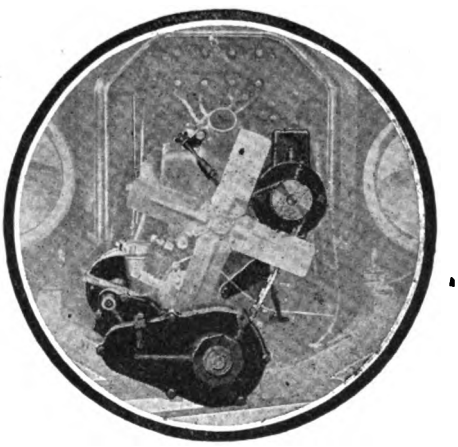
Look at Any Ford Engine—

Carefully note the *front-end suspension*— then you'll see why the only satisfactory *starter-lighter* for Ford cars is one that



First—Distributes its weight equally on both sides of the engine.

Second—Does not strain the *front support* when cranking or generating.

That's Why Ford Mechanical Design Demands

A·B·C
Two Unit
STARTING & LIGHTING SYSTEM

(Made Expressly For Ford Cars)

Doesn't it stand to reason that a starting and lighting system built to fit a Ford is the best system for a Ford? That's an axiom—not a mere statement. The dealer who sells a "make-shift" sells dissatisfaction. The A. B. C. Starting and Lighting System for Fords, readily adapts itself to Ford design. Its units (one on either side of the engine) insure perfect balance. It is chainless. No drag or strain from starting or generating. Operates under all conditions. Does not lessen speed nor power. First, we proved these truths on thousands of Fords. Now, we're equipped and ready to supply the largest possible demand.

Be SURE the starter YOU sell will make good. You cannot be sure unless it's an A. B. C. Easy to sell—easy to install—easy to make money—if you represent the A. B. C. Ask, today, for our "ON AND OFF YOUR SHELVES" policy; descriptive sales plans, prices, terms, discounts and liberal proposition to A. B. C. distributors.

A·B·C STARTER·COMPANY DETROIT

Performance
Sells better than claims

Claims over the counter may make sales, but performance in your customers' cars makes resales.

Dealers who are after the profitable resale business should familiarize themselves with the records of

RAJAH *SPARK PLUGS*

Rajah Plugs are not standard equipment for Hudson cars, but before Mulford drove his Hudson up Pike's Peak in the record-breaking time of 18 minutes and 24¾ seconds—*he changed to Rajah Plugs.*

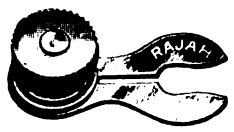
In all hill-climbing contests and gruelling road races, Rajahs always outnumber any other plug. When a Chalmers car driven by Joe Dawson recently covered a straight-away mile at Jacksonville, Fla., in 38.1 seconds, Rajah Spark Plugs were used.

The plug that meets these exceptional tests is the one to talk up over the counter, confident that it will make good in your customers' cars.

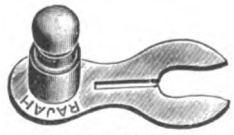
Address RAJAH, *Bloomfield, N. J.*

HUGHSON & MERTON, Inc., San Francisco, Los Angeles, Portland, Seattle — JOHN MILLEN & SON, Ltd., Montreal, Toronto, Winnipeg, Vancouver

RAJAH TERMINALS AND ADAPTERS are furnished with Rajah Plugs so that they can be used with any car not equipped with the Rajah type of Clip Terminal.



RAJAH TERMINALS



Rajah Regular Clip Terminal
Adjustable to any cable. With the extra collar supplied fits any make of plug.

Rajah Ferrule Clip Terminal

Gasoline
"pumped" by air
no labor

A Gasoline Delivery System That Protects Buyer and Seller

Operated by Air Pressure

The many advantages and practical improvements embodied in the "APSCO" Gasoline and Oil Storage and Distributing System eliminate all waste and guess work, reduce labor-cost and give adequate protection against danger from fire and explosion.

Simple Economical Safe

Approved by the Board of Fire Underwriters

Simplicity of construction and operation is secured by discarding cog-racks, pinions, bearings, pistons, cup leathers, piston valves and gearing. Wear and tear are reduced to a minimum. The air-pressure system secures a responsive flow of oil or gasoline to any desired point of use—direct from the storage tank to vat, tank or machine—without the use of labor, pumps or any auxiliary mechanism.

SPECIAL APSCO METER

Approved by the Department of Weights and Measures of the City of New York

This "APSCO" meter measures the actual amount of oil or gasoline sold or consumed. Shows at a glance the exact, individual quantity drawn off, and the total amount used.

The APSCO is Easy to Install

The "APSCO" System is adapted to the multi-storied garage, or the smallest one. It may be installed in old or new buildings. Old style systems can be changed over. The cost is moderate, and varies with the amount of piping, the size of storage tank, and the number of outlets.

Our staff of engineers and designers is at your service, and is ready to furnish careful estimates of the cost of installing the "APSCO" System to meet any particular requirements.

10,000 MILE GUARANTEE Backs This Tire

Every Brictson Pneumatic Tire is sold under a specific 10,000 miles written service guarantee. This guarantee is the ***longest*** and the ***strongest*** ever put behind a pneumatic tire. It is the result of ten years' experience and is a positive protection to every purchaser. Try Brictson Tires on your car at our risk and learn how to cut down your up-keep costs.

"ABSOLUTELY PUNCTURE PROOF"

Brictson Tires are puncture-proof, blowout proof, skid proof, rut proof, rim cut proof, oil proof and gasoline proof. Wonderful resiliency and easy riding qualities as well as economy commend them to car owners. The service and satisfaction they give is rapidly extending their sale.

Retread Your Present Tires

If your present tires are new you should by all means apply Brictson Treads, or tire protectors, thereby making them puncture proof—rut proof—rim-cut proof—gasoline proof and non-skid.
If your present tires have been used and the rubber tread has been worn off or thin, you may get additional service by applying Brictson Treads, also making them puncture proof, oil proof, rut proof, gasoline proof and non-skid.

Free Trial Offer

To convince you that Brictson Tires will give you satisfaction we will let you try them on your car at our expense. Write today for conditions of this Free Trial Offer and full information about Brictson Tires and Brictson Treads.

"THAT'S GOOD! I'LL BET IT'S A YANKEE INVENTION!"

-YES UNCLE THAT'S THE YORK CARBURETOR PERFECTOR

This Wonderful Device Positively Insures

Guaranteed Gasoline Economy

Absolutely guaranteed to do all we claim or your money promptly refunded. We take all the chances.

The York Carburetor Perfector operates by the speed of the gas as it passes through to the manifold, striking the cone-shaped screen, breaking up the mixture or vaporizing the gasoline, and admits air AUTOMATICALLY with the speed of the motor. Helps minimize carbon too, and produces a smooth, sweet running motor.

IT'S A SUCCESS—NOT AN EXPERIMENT!

No Holes to Bore—No Changes to Make.

Fill out this coupon now, enclose $5.00—If you're not perfectly satisfied in 10 days, send it back. Thousands in use—put one on your car and smile.

Temme SPRINGS FOR ALL CARS

THE picture tells the story. Are *you* the Mr. Smith of Smithville? Are *your* highway signs on all your roads?

Do all the lame cars drive to *your* door for Temme Springs and other things?

If *you* are not Smith, who is? Or who will be? That's the question.

And in most good towns it will be answered soon. For Temme Springs and Temme's Triple Action Service are known to be *as good as gold.*

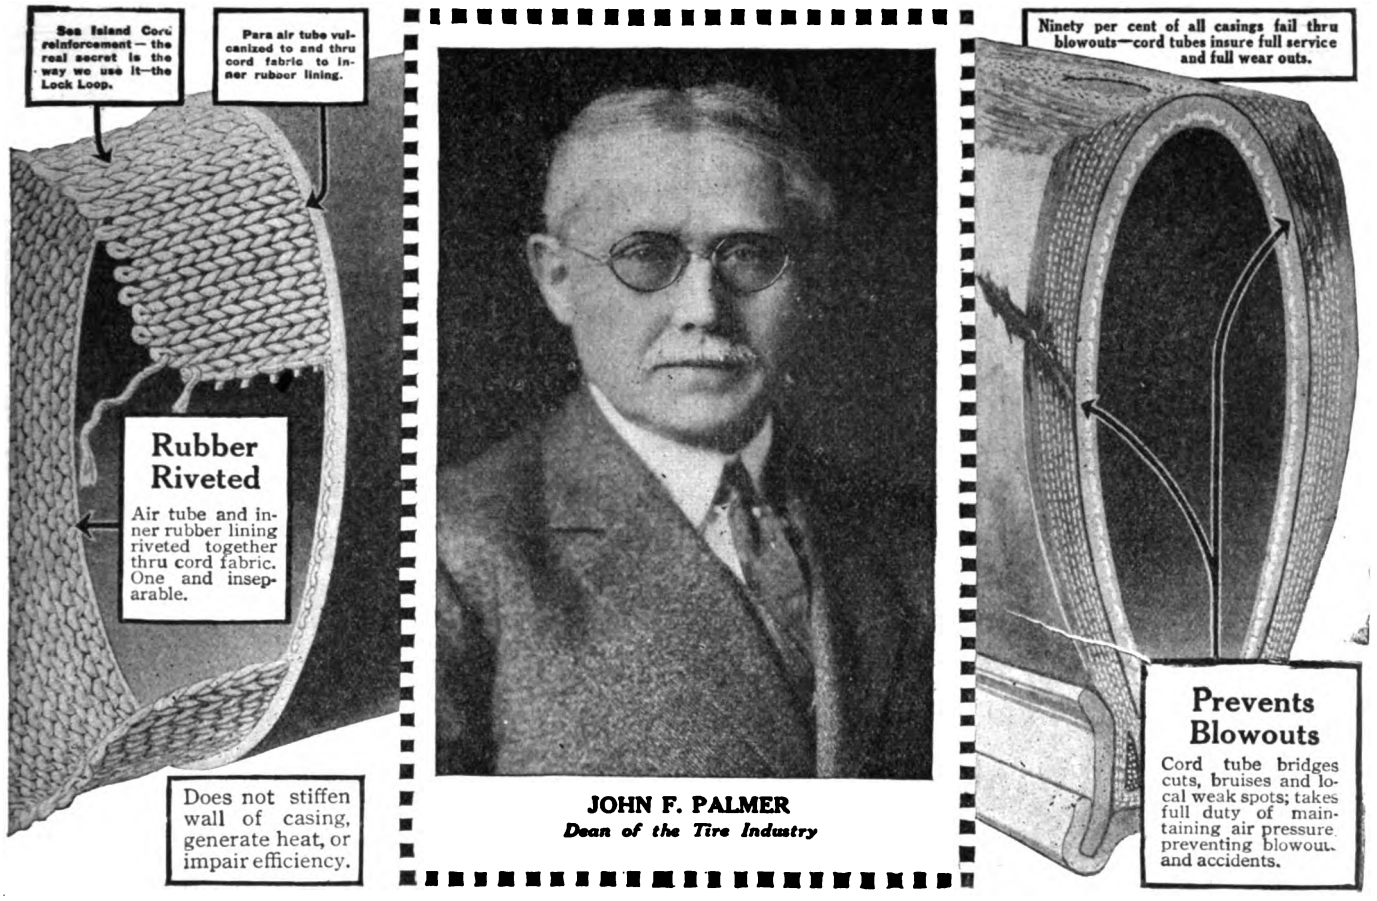
Hundreds of repairers, who have "banked" on Temme and never lost, are putting up these Temme highway signs today.

These signs *will* bring in business. Temme has tried them, so he *knows.* And now he offers *you* what won for *him.*

Temme Springs *"for all cars"* means just what it says—for all cars *since 1902.* Test us by naming the spring you need. Temme Triple Action Service will have it on the way to you the same day.

"For all cars" means *designed* for all cars to factory specifications. And so good are Temme Springs—so prompt the service—so fair the prices—that dealers in *all* cars now buy from Temme *in preference* to the car maker.

You need these springs, this service, these signs. They will make you money, bring new business, help you build the good reputation you are after.



If you delay you may lose this exclusive proposition. Write or wire us now, saying: "Send Temme Spring Service Station proposition at once."

JOHNSON
Shock Absorber

This is to remind you of the new model of the famous Johnson Shock Absorber—made by us. The only cure for a hard riding car is a pair of Johnsons. Temme Spring Service Stations make good money on them. Write now for our new proposition.

John F. Palmer Offers His Latest Tire Improvement

JOHN F. PALMER, better known as the Dean of the Tire Industry, has added another remarkable invention to his long list of tire improvements—the Palmer Safety-Cord Inner Tube.

This tube possesses properties that are found in no other tube. Blow-outs are practically done away with. Casings in which these tubes are used give, on an average, **of double their normal mileage.** These tubes are manufactured by Mr. Palmer's own company, a strongly and satisfactorily financed organization, which has been delivering its product on a steadily increasing scale of production for many months.

Unusual Sales and Profit Possibilities

Dealers whom the trade knows for the success and business judgment are selling Palmer Safety-Cord Tubes. The success they have had with them has surprised even those keen-minded business men. The motoring public has set its stamp of approval on these tubes.

We want more dealers of this type. We want men of exceptional standing in their communities to add to their reputation as distributors of quality merchandise by selling Palmer Safety-Cord Tubes. We are going to back up the efforts of these men with strong, sizable, convincing advertising in newspapers, magazines and trade papers. Advertising has already started. It will be continuous.

Write or wire for details of liberal selling proposition.

PALMER TIRE & RUBBER CO. St. Joseph, Mich.

Palmer Safety-Cord Tube

Lock-Looped Construction

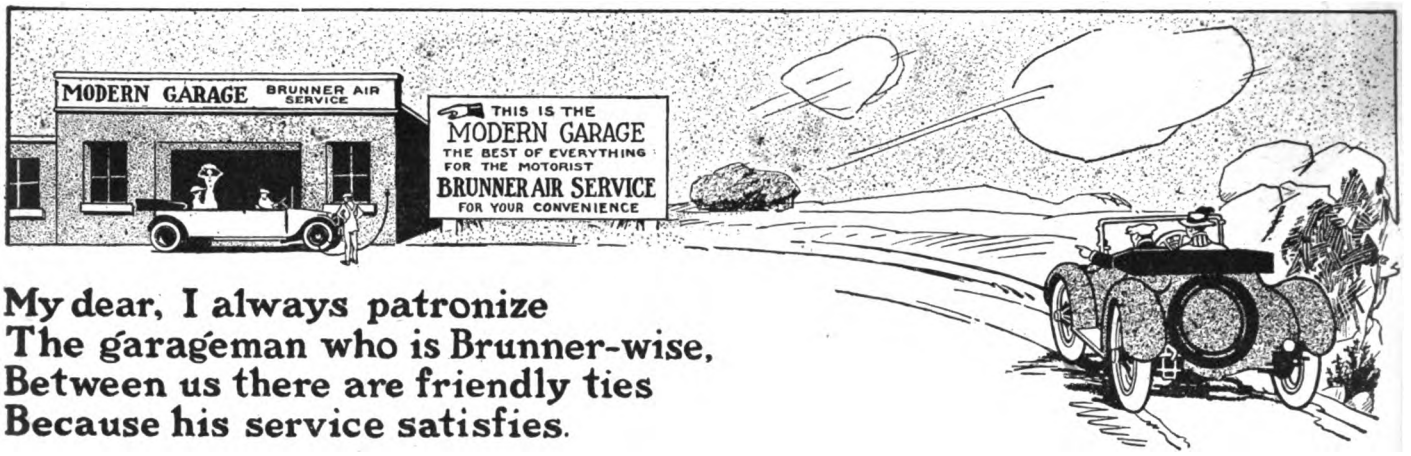
A "moulded" tube carrying an inner cord structure, which gives it great strength without interfering with its resiliency. Cord structure is Lock-Looped on special machines, patented and used by us exclusively. Fashioned on a double curve it fits the cavity of the casing perfectly without stretch at the tread or wrinkle at the rim side.

Greater Tire Mileage

Cords carry a designed portion of the strain formerly carried by the casing alone. Thus relieved, it is obvious, casings will run further and give better service.

"Mothers the Casing"

The air tube proper is riveted through and moulded over these cords on similar curves. Inflated, Palmer Tubes have the same thickness of rubber on the tread as on the rim side. They are not thinnest on the side nearest the road.



Lock-Looped construction of cords permits slight stretch in any direction, so that the tube is able to instantly conform to the myriad changes in the shape of the casing caused by load and road inequalities. This enables the tube to instantly bridge over a STONE CUT or BRUISE in the casing, preventing BLOW-OUT that would otherwise ensue, by assuming the strain at the very point needed and always "mothering the casing" against damage and deterioration.

Repairs

Repairs are made from the outside, exactly the same as in ordinary tubes. A cold patch or vulcanizing as you desire. It is not necessary to touch cord structure. Tubes do not stiffen the casing or impair its efficiency in any way.

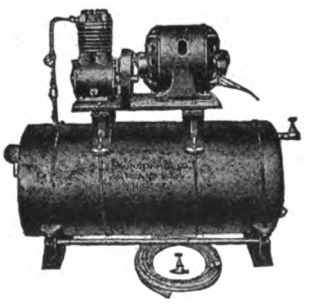
PALMER SAFETY CORD TUBE

Digitized by Google

My dear, I always patronize
The garageman who is Brunner-wise,
Between us there are friendly ties
Because his service satisfies.

Mr. Garageman, is your equipment modern? Are you securing your share of the motorists' trade, or is a large portion of the trade driving by your door simply because they do not know you are awake and on the job?

If your business is not what it should be, why don't you install a Brunner Air Compressor in your garage and advertise the fact that you are in position to render Brunner Service by displaying a Brunner sign on your garage?



The Brunner Sign Attracts the Trade of the Brunnerwise Motorist

Because he knows that the garage displaying the Brunner Sign is always prepared to render him prompt and efficient compressed air service—he knows that when he pulls up under the Brunner Sign he never has to drive away disappointed. That is why the trade of the Brunnerwise Motorist follows the Brunner Sign.

Mr. Garageman, time was when you could "get by" with indifferent service, but the time is here when Brunner Service is essential if you desire the trade of the motoring public which does not patronize the garage which is merely "getting by"—we mean the Brunnerwise Motorist.

Mr. Garageman, your compressed air service is "your one best bet" and if it is not right up to the minute then you are behind the times and the Brunnerwise Garageman has something on you. The efficiency of your establishment starts at the end of your air hose. Your income is regulated by that efficiency.

INVESTIGATE THE BRUNNER AIR COMPRESSOR

Be honest with yourself and investigate the garage air compressor situation thoroughly before deciding on your new equipment. The Brunner will stand investigating and the more thorough the investigation the more certain will be your decision in favor of Brunner Service, because it not only insures compressed air efficiency of the very highest order, but it also insures that very desirable and liberal patronage of the Brunnerwise Motorist, which follows the Brunner Sign.

We will be glad to send you the name of the Brunner Jobber who covers your town, also our catalogue and Garageman's Handbook on Compressed Air—a book which every garageman should read carefully. They are all free for the asking.

SUNDERMAN
Vacuum Carburetor

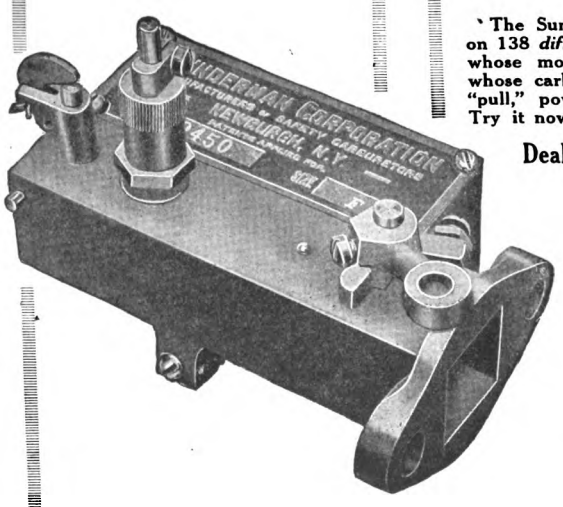
$5

F. O. B.
Newburgh

$6.50 for
other than
Ford or Metz

The dealer who has the Sunderman agency in your territory will have the jump on the other fellows—why don't YOU try for it?

Flexibility



The longer a man drives a car the more anxious he is to have a flexible motor. He wants to "play" with it—throttle it down to a crawl in city traffic, make it leap out of the crowd a nose ahead of the livest car in the jam; he wants it to pick up rapidly, to give him a spitfire burst of power when there's a danger of taking the other fellow's dust. And when he reaches an open stretch of country, far from the traffic cop or the lurking country constable, he wants the roaring drive that spells speed.

THE SUNDERMAN CARBURETOR GIVES JUST THAT KIND OF FLEXIBILITY

It's all in the mixing principle—scientifically and exactly worked out in the Sunderman construction. Taking gasoline from the multiple jets as slowly or as rapidly as the motor suction demands it; drawing the air in at right angles, "fanning" the gas as it leaves the 45-degree nozzles, breaking it into inconceivably small particles before it reaches the manifold; giving as much or as little as the need indicates, the Sunderman Carburetor sends *gas* to the combustion chambers, where instantaneous explosion extracts the last atom of pep and punch from the gasoline, getting *more* power from *less* fuel.

Buy it now for Flexibility—
Get Power, Pick-up and Proved Economy as good measure

The Sunderman Carburetor has made good its every claim on 138 *different* makes of pleasure cars and trucks—"orphans" whose motors were ready for the junk heap, modern cars whose carburetors were anemic, trucks whose owners wanted "pull," power and economy. It will make good for *you*. Try it now.

Dealers: We want you to get the benefit of our advertising—write for territorial proposition

Little Giant Trucks

Are You the Man?

We are looking for one man, a man of exceptional ability and initiative. Some one man, above all others in every community, has the particular ability we seek. When we find him, he will immediately begin to build, with our aid, prestige and profit for himself.

He will be the highly capable representative of a highly capable motor truck. Little Giant.

He will be backed by a world-spanning organization, that has 23 years' reputation and experience in the building of engineering tools and machinery. He will be backed by the record that thousands of their trucks have made in over 175 varied types of business endeavor. He will be backed by the proof of service that many of these trucks have given for over nine years. He will be backed by intensive local newspaper advertising over his name, in his territory. He will be backed by a truck, whose specifications set so high an efficiency standard, that it represents the most desirable hauling-equipment purchase that can be made by men who have things to move. He will be backed by a complete line—1-Ton, 2-Ton, 3½-Ton, and Convert-a-Car (Ford truck unit); and their extra exclusive cost-cutting feature—the Duntley Hydro-Pneumatic Gas Generator, which burns half kerosene and half gasoline, cutting fuel cost in two.

Write today, or better still, telegraph your belief that you are the alert, progressive, capable man we want; that you can ably represent in your community the Little Giant Trucks with the habit of heavy performance. Made that way by the $14,000,000

"Tug O' War"

MAKE this test. Take two Firestone Cementless Tube Patches and stick them together. Then try this "tug of war." Pull, yank. They will hold fast.

Here you have a practical demonstration of the strength and holding power in this Firestone accessory. It proves, with A.B.C. simplicity, that here is a motoring essential which you cannot afford to miss.

Small as they are, these Cementless Tube Patches are representative of Firestone "know-how" and care in building. They are hand-buffed and feather-edged; will not pucker or creep, and they hold indefinitely.

Dealers: Tie trade tight to you. Make the motoring public your everlasting friends by selling these big helps for little troubles. Our co-operation is always at your service. Write for information.

"KEEP THE CAR ON THE GO"

Friction starts Grinding before Grease begins Lubricating

Common grease needs heat to soften it before it can lubricate. The parts grinding together must furnish this heat in the shape of friction. Meanwhile these parts get no lubrication. And Friction—getting a good start—is *never* caught up with by grease.

TRADE MARK REGISTERED IN
NON-FLUID OIL
UNITED STATES PATENT OFFICE

Lubricates Instantly—and Always

NON-FLUID OIL lubricates the second your car moves from rest—and every minute it is in motion. Doesn't give friction a chance to start. It never melts, never leaks out, is much purer and longer lasting than any grease you can buy.

If you buy lubricants on the same basis that you buy tires—purely on *service*—you'll ask for NON-FLUID OIL *every time.*

Get "K-00 Special" grade for gears; "K-000" grade for bearings. Sold at your dealer's in orange-colored cans only.

Write for a free booklet, "Lubrication of the Motor Car."

U. S. Two-Stage Air Compressors U. S.

DEFINITE 14 ADVANTAGES

The following briefly described advantages of the United States Two Stage DE LUXE Automatic Air Unit place this outfit on a plane of refinement and superiority unequalled and unapproached by any other air compressor.

No. 1 *The Two Stage Feature.* Increases efficiency, requires less power and assures slow depreciation.

No. 2 *Intermediate Starting Tank.* Automatically permits motor to start against no pressure, thus eliminating the cause of burned out motors.

No. 3 *The Filtering Trap.* Extracts all moisture or oil, assuring pure, dry air, free from oil.

No. 4 *Automatic Control.* Maintains desired pressure in tank without any attention whatever.

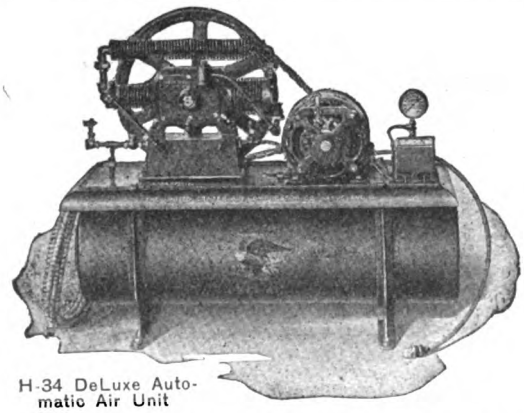
No. 5 *Safety Valve.* Prevents overcharging of tank.

No. 6 *Intake Silencer.* Muffles the undesirable noise common to air compressors.

No. 7 *Inter-Cooler.* Prevents overheating of cylinders.

No. 8 *Cylinder and Crank Case En Bloc.* Assures perfect alignment and avoids leakage of oil.

No. 9 *Specially Designed Balanced Check Valve.* Makes an absolutely tight valve that will last practically a lifetime.



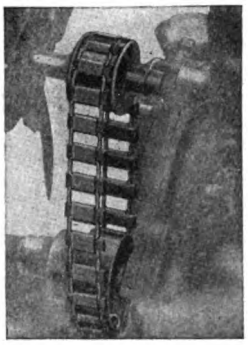
No. 10 *All Metal Base.* Cannot warp or split.

No. 11 *V Belt.* Quiet running, durable and eliminates use of idlers or belt tighteners.

No. 12 *Motor Adjustment.* Permits taking up any slack in belt by turning adjusting screw.

No. 13 *Outfit complete and ready to run* when pipe is attached and plug screwed into light socket.

No. 14 *An Unequalled Guarantee with every outfit.*



H-34 DeLuxe Automatic Air Unit

In addition to the air unit described above we manufacture a most complete line of air compressors of both Double and Single Stage. Literature on request.

PIERCE Governors

FOR FORD CARS

The owner's hand controls the speed of every Pierce equipped Ford truck or delivery wagon, no matter when or where it is driven. It makes no difference who the driver is, he cannot exceed the speed for which the governor is set—and the owner decides the speed.

A Pierce Governor don't cripple the motor when heavy loads, steep grades, or slippery traction demand extreme power. It is the only governor made that will control the speed of a Ford truck, and leave the motor entirely free in reverse and low gears.

Stop fast driving and you eliminate 75% of all collisions and accidents - reduce repair costs one-half —and make tires wear longer. Pierce Governors pay for themselves a dozen times a year.

A Live Proposition for Live Dealers

PIERCE GOVERNOR COMPANY

AKRON-WILLIAMS

EACH and every piece of Akron-Williams Tire Repair Equipment has been designed and brought to perfection with the active aid and co-operation of experts employed by the Akron Tire Factories—the largest in the world. These engineers work side by side with us to develop the most efficient Tire Repair Outfits, **firstly,** to use in their own factories, and **secondly,** to sell and recommend to their dealers and agents throughout the country.

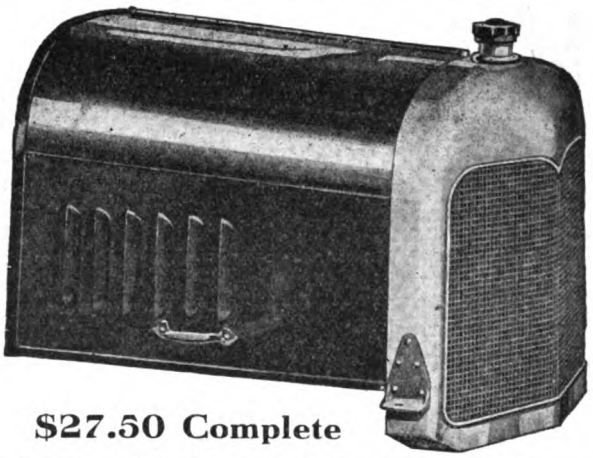
As a result, Akron-Williams Tire Repair Equipment is always the latest and most improved. The Repair Outfit we offer you is the same in every way as used, sold and recommended by more than 60 leading Tire Manufacturers.

Akron-Williams Outfits are built to make the most efficient and lasting tire repair in the shortest possible time—the kind of work that builds trade and profits. No essential tools are lacking. Nothing needless is included.

Start Right—with Akron-Williams Equipment

More than three million cars are now in use; over a hundred million dollars is being spent this year for tire repairs. Tire repairing offers wonderful opportunities either as a separate business or a department of a garage or supply business. A few hundred dollars will start you. BUT—**your success depends absolutely upon the equipment you choose.** Start right—don't experiment—use the equipment all leading tire companies use, recommend and sell.

NOTE: We do not take any other outfits in exchange. Write for Free Booklet, "Your Share of the 100 Million Dollars."



"Everything for the Tire Repairman."

Just out—our new catalog illustrating full and complete line of tire repair machinery, equipment, tools, etc., for every size shop. Brimful of new time and labor-saving devices. Write for it today.

Automatic Feeding
For Large and Small Drills

"Yankee" Tools Make Better Mechanics

This "Yankee" Bench Drill

automatically exerts just the right pressure to do the work in quickest time without smashing drill points.

You can use the largest drill the chuck will hold, or the smallest, and do the work without paying any attention to feed. Set drill on Friction Feed and bring drill point in contact with job, then shift lever and Ratchet Feed automatically maintains an even, uniform cutting pressure until the job is completed.

Can't jam gears or smash teeth. Table is adjusted by hand screw and bracket, or removable. A big range in size of work is possible, making this **"Yankee"** Bench Drill exceedingly useful to garage and repair men.

"Yankee" Bench Drill

No. 1003—One Speed—18¾ inches high, holds round shanks to ¼ inch diameter.

No. 1005—Two Speeds—28 inches high, holds round shanks to ½ inch diameter. Three-jaw hardened tool or steel chuck. Price at Factory,

No. 1003 - - $10.00 No. 1005 - - $16.50

"Yankee" Vise No. 990

Convenient for holding irregularly shaped work on table of Bench Drill. Machined at right angle on bottom, sides and end.

Price, **$2.20**

Your dealer can supply you.

GORDON
Seat Covers
TAILORED TO FIT

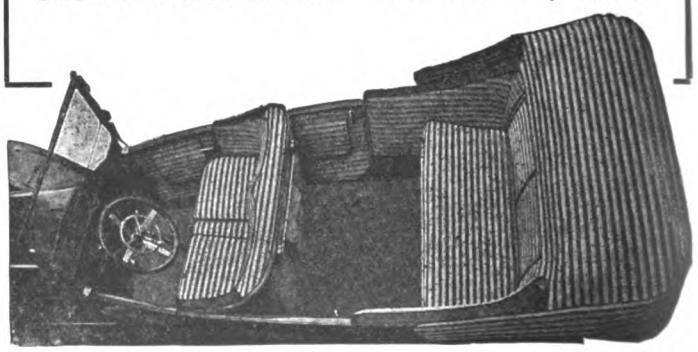
are coming into more general use every day.

They are a luxury in summer because of their fresh, smooth coolness, and a protection in winter from the chill of cold cushions. Save wear on upholstery and protect motor togs from grease and dirt. Add, too, to the resale value of a used car—actually put money in a man's pocket when he turns in his present model toward a newer one.

Gordon Covers are made for every American car and every model. They are guaranteed to fit. Twenty-four distinctive Gordon fabrics are used—lovely shades of brown, tan and gray, in striking and original patterns. Wise motorists go to their accessory dealer and pick the pattern that suits them best—or—write us to send, without cost, a handsome booklet printed in actual tints, describing Gordon Covers and giving the price of a set for their motor car in any of the fabrics.

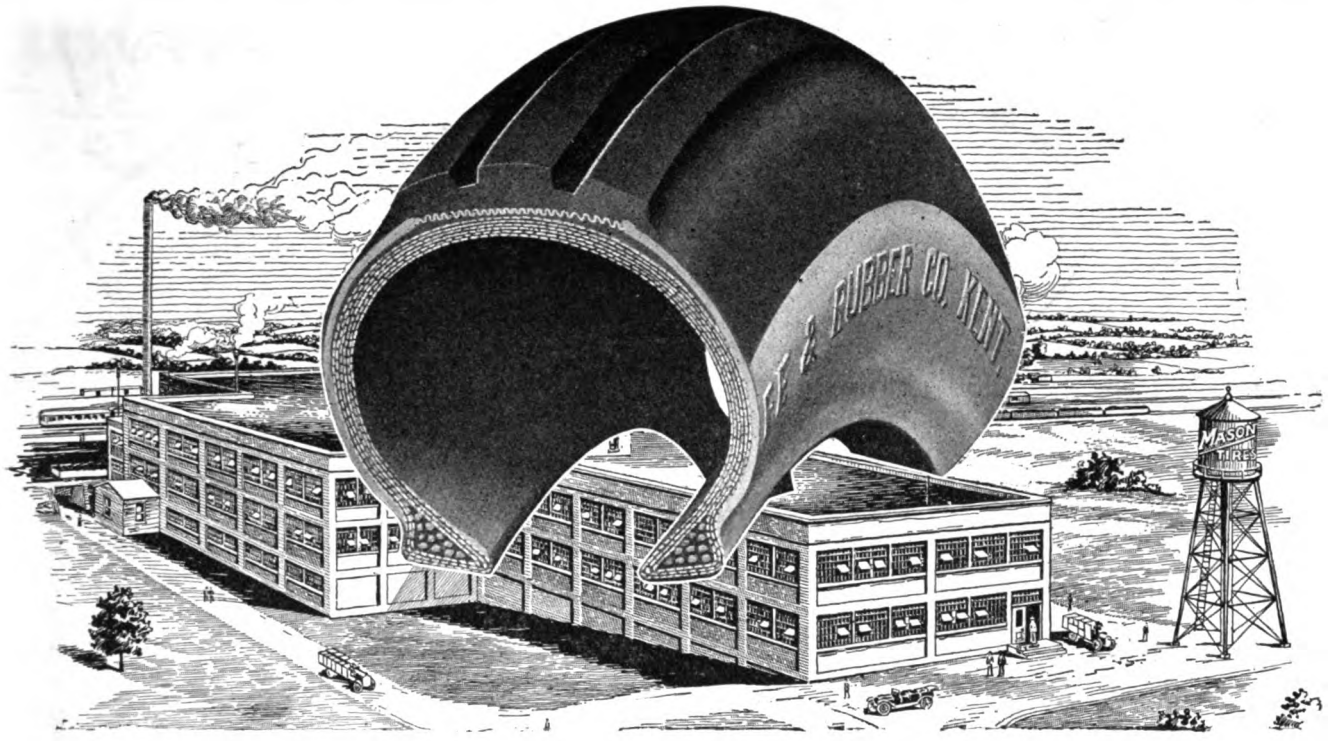
Gordon Easy On Tire Covers

As name implies, easiest of all covers to put on. Fit all tires and every type and kind of holder.



Dealers:—Read This

There is nothing in the automobile accessory line today, more attractive from the dealer's standpoint, than Gordon Seat Covers. Their beauty, utility and undoubted economy are making seat cover converts every day.



Give Gordon Seat Covers and Gordon Easy On Tire Covers a prominent place in your business and you may be sure of a ready reception for them and satisfactory profits for yourself.

Let us hear from you!

BATTERY RECHARGING.

Lines of Force, Current, Coils, Speed and Variable Resistance.

BY SYDNEY F. WALKER, M. E.

No. 3.

Before going farther, it may be useful to explain as far as is possible what is meant by lines of force. As is well known, it was a conception of Faraday's, and he used the idea to enable measurements of different strengths of magnetism, and of magnetic fields to be made. He conceived that a number of lines were created in the neighborhood of a magnet, and inside the magnet, in which the power resided of causing minute steel magnets to turn in their direction, to lie along the lines of force; different strengths of magnets and of magnetic fields were to be measured by the number of these lines that existed in a given space. Modern electrical engineering has introduced very exact quantities, carrying out Faraday's idea. A line of force has the property of causing a minute steel magnet, the unit steel magnet, to lie along itself. When a current of electricity passes round a bar of iron it creates lines of force in the bar and in the immediate neighborhood, such that the minute steel magnets would be caused to place themselves at right angles to the direction in which the current is flowing. This means, of course, that when a bar of iron has a magnetizing coil around it, the lines of force are in the direction parallel with the length of the bar. As mentioned above, the number of lines of force is very large, and measurement is reached by supposing that a certain number of them from 10,000 upwards are accommodated in every square inch of an iron or steel bar, or any other part of a dynamo through which the lines of force pass, including the air space between the revolving armature and the field magnet poles.

Current for Lamps and Battery.

The problem is complicated by the fact that lamps require pressures of 12 volts or 6 volts, according to the system employed, while the current furnished by the dynamo for charging the accumulator might be 15 or 16.5 volts, or the corresponding figures for the 6-volt service. This part of the problem looks very awkward at first, and in the matter of train lighting plant, it has received special attention, an electrical resistance being always inserted between the dynamo, or the accumulator, and the lamps when the lamps are burning. With the automobile plant, in England at any rate, it has not been found necessary, the same properties of the shunt machine having overcome the difficulty, aided by special construction on the part of the lamp makers. The light is given out, in an incandescent electric lamp, by the Tungsten filament, which is raised to a temperature of 2,000 degrees C. odd. The amount of light furnished depends directly upon the extent of surface of the filament, and upon the temperature at which it is burning. An increase of pressure produces rather a rapid increase of light, because the increase of temperature is also rather rapid; the increase of temperature with a Tungsten filament lamp is at a lower rate than with a carbon filament, because the electrical resistance of the Tungsten filament rises with the temperature, and chokes back a portion of the current that would otherwise flow, while with the carbon filament the resistance falls with an increase of temperature, and so encourages a larger

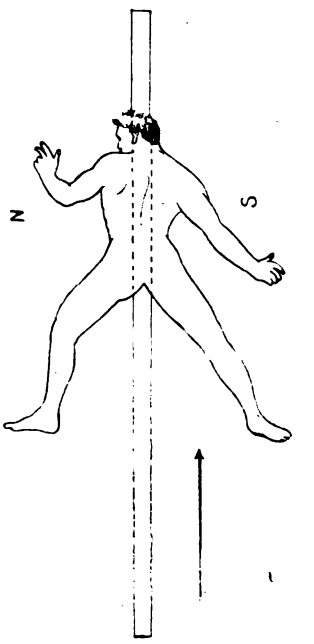

Fig. 12—Diagrammatic sketch showing how to tell in which direction a bar of iron or steel is magnetized, with a given direction of current flowing through the magnetizing coils. The experimenter is supposed to be swimming in the current, and in the same direction as the current is flowing; under those conditions the N. seeking pole is always on the left hand, and the S. seeking pole on the right.

flow of current. What lamp manufacturers had to consider was how to provide a lamp that would stand the pressures likely to rule at the brushes of the motor car dynamos without reducing its life, and without appreciably reducing the light given. The rapid increase of the temperature of the filament, due to increased pressure, seriously reduces the life of the lamp, while it increases the amount of light given, though only for a short time. As the writer understands the matter, the incandescent lamp makers have constructed lamps to run at 13 volts, or 6.5 volts, according to the system employed, and that, combined with the self-regulation of the shunt-wound dynamo, solves the problem. Supposing that a dynamo is charging the accumulator at the time the lamps are switched on; the increased current flowing through the armature will lower the pressure at the dynamo brushes, so that the pressure at

Digitized by Google

the lamp terminals may not be above the 12 volts; if it is 12.5 volts, with lamps made for 13 volts, the life of the lamp will be considerably increased, while the light given will not be seriously affected. Under these conditions, too, the accumulator would commence to discharge, and to furnish part of the current required for the lamps, so that the pressure at the terminals of the lamps will be maintained at about the required figure. It should be mentioned that it is always wise to run electric incandescent lamps a trifle below the pressure they are made for, as it adds considerably to their life, while running them even a very small percentage above their pressure seriously reduces their life. From the moment current passes through a lamp, two actions commence, both of which tend to put it out of service; the filament itself tends to break up, minute portions of it being thrown off from its body, by the action of the current, and these minute portions are bombarded on to the inner surface of the containing globe. The result is, the substance of the filament becomes less and less, a smaller and smaller current passes through it, its surface being smaller and smaller, and therefore the light given by it being less and less; and the bombardment of the small particles of the filament upon the glass gradually obscures it, so that more and more of the light rays are absorbed by it.

In England 12-volt services are more the rule, while, the writer understands, in America 6-volt are preferred. So far as the incandescent lamp is concerned, there is a great deal to be said for the 6-volt lamp; the filament is shorter and thicker, and should therefore stand the vibration of the motor car better; on the other hand, the joint for a 6-volt lamp, though it is more easily made, may absorb more of the heat delivered by the current to the filament. One of the difficulties in the way of the manufacture of low-power incandescent lamps, to work with low pressure, is the fact that the two joints between the filament and the platinum wires leading to the lamp cap, and also the cap itself, absorb a considerable portion of the heat delivered by the current to the filament. It will be remembered that the filament is in mechanical connection with the joint, and with the lamp cap, and therefore there will be a flow of heat from the filament at the higher temperature to the joint and cap at the lower temperature. The cap will, of course, always be at a lower temperature than the filament, because it is dissipating heat to the surrounding atmosphere, and usually at a fairly rapid rate. Convection currents will be set up at the metal surfaces of the cap, which will carry off a considerable quantity of heat, and this will be intensified by the draught of air created by the passage of the motor car through the air. Of course, all this applies to the 12-volt lamp, but in that case the heat delivered to the filament is distributed over a larger area, and the mass of the joint is smaller.

Dealing With Variation of Speed.

In the writer's view, the variation of speed can be quite efficiently dealt with by the design of the shunt-wound dynamo; but a number of methods of handling the problem have been worked out, and he proposes to examine them in detail. The first method, and the one he believes to be more generally employed than any other, is the use of the "bucking coil." Like so many other expressive terms, it hails from your side of the water; and it means a coil of wire, consisting of a few turns of very much thicker wire than that employed for the shunt winding of the field magnets, the thick wire being also wound round the field magnets, but in such a manner that the action of the current flowing in it opposes the action of the shunt-field coils. The method is an adaptation of a very old device that has been employed in connection with continuous current dynamos, almost from the earliest period of their manufacture. When electric lighting was first introduced for buildings, etc., and separate dynamos were employed for the purpose, the shunt-wound machine was at first made use of; but the fall of pressure at the brushes, as the current furnished by the dynamo increases, made the arrangement very inconvenient. It meant that as lamps were turned on, the light given by each individual lamp became less and less, unless the speed of the dynamo was increased at the same time, which, of course, could not easily be done. To meet the case, a few turns of thick wire were wound on the field magnets, outside of the thin wire coils of the shunt winding, and the whole of the current flowing to the lamps passed through these thick wire coils. The thick wire coils were calculated to create a sufficient number of lines of force in the armature core, and the space in which it revolved, to make up for the drop in pressure at the brushes; that is to say, to bring the pressure at the brushes back to the normal figure. The magnetizing effect of the series coil, as it was termed, was also arranged to provide for the drop in pressure due to the charge for the passage of the lamp current through the series coil itself, the pressure at the brushes was made a little above the normal pressure, when the lamps were in use, so that the pressure on the lamp service remained constant.

It is obvious that the series coil can be made to reduce the number of lines of force in the armature core, etc., by causing the current flowing in it to act in the opposite manner to the current flowing in the shunt coil. Perhaps a little explanation may be of service here. When a current of electricity flows through a wire that is coiled round a bar of iron, such as the core of the field magnet of a dynamo, it makes one end of the core north seeking, and the other south seeking. There are many methods given in the text books for distinguishing which end of the core will be N and which S; but the following is the one the writer prefers. Imagine one's self to be lying on a wire through which a current is flowing, one's body if necessary being doubled round the iron core, and imagine the current to be flowing along the wire from one's feet to one's head, as shown in Fig 12; the N pole will always be on one's left hand and the S pole on one's right hand. In winding the coils of the field magnets for dynamos the wire is coiled on in exactly the same manner for both the core which has its N pole facing the armature, and that which has its S pole facing it; the current is directed in the proper direction to make one north and the other south, by connecting the ends of the coils so that the flow is in the direction required. In practice the coils fall into place without any difficulty, because they are opposed in position within the containing cylinder. It will easily be understood that by winding the coils of thick wire in the opposite direction to the thin wire

Digitized by Google

coils, a portion of the magnetizing effect of the thin wire coils may be neutralized; it will be seen also that as the current flowing in the thick wire coils is very much larger than that in the thin wire coils, a comparatively few turns of the thick wire coils will do all that is required. It will be remembered that the magnetic pressure is measured by the ampere turns, the product of the number of turns of wire through which the current is flowing, and the strength of the current itself; thus supposing there are 1,000 turns on the shunt-wire coils, and the current flowing in them is 1 ampere, the magnetic pressure will be 1,000 ampere turns. If the current flowing to the accumulators and the lamps is, say, 10 amperes, it would only need 100 turns to completely neutralize the magnetic effect produced by the shunt coil. In practice, of course, only a few turns are employed, as the effect required is only sufficient to neutralize the surplus pressure, the surplus lines of force due to the surplus speed and the surplus speed itself. Ten turns, for instance, would

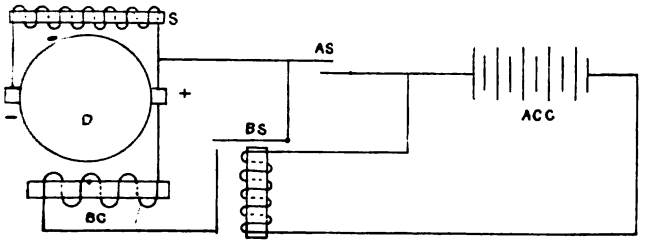

Fig. 13—Diagram showing the connections of the writer's proposed arrangement for bringing the bucking coil into operation when the pressure reaches a figure that would overcharge the battery. To fully complete the sketch a line should have been drawn down from the extreme left and along the bottom to the coil under the letters BS.

give a "bucking" pressure of 100 ampere turns, which would probably be sufficient for all purposes. But in the writer's opinion there is a serious drawback to the use of the "bucking coil" in the manner in which it has generally been employed, viz., with it always operating, from the moment the auto switch closes the outer circuit, connecting up the dynamo to the accumulator. A little consideration will show that if the "bucking coil" is always connected, it will be acting against the shunt coils from the moment the auto switch cuts in, and therefore the magnetic pressure produced by the shunt coils will have to be greater than would otherwise have been necessary, in order to allow for the neutralizing action of the "bucking coil." This means that the efficiency of the machine will be lower, and there is not much room for a lowered efficiency in these small machines; it is necessarily rather low at the best. And there is another point that may be rather serious; the magnetic pressure produced by the shunt winding of the dynamo depends directly upon the gauge of the wire, and nothing else; it increases as the gauge increases, and vice versa. Adding to the number of turns of a shunt winding does not add to the magnetic pressure the shunt coil produces, because the increased number of turns are balanced by the increased resistance of the additional length of wire used; it may happen also that an increased length rather lowers the magnetic pressure, because as it will be applied on the outside of the coil, its magnetizing effect on the core will be less than that of turns nearer the core, while the length of each turn will be greater than those nearer the core. In practice it is taken as an axiom that the magnetic pressure varies with the gauge; and if the "bucking coil" had any appreciable effect upon the magnetic pressure, it would mean that a larger gauge of wire would have to be employed for the shunt coil, taking a larger current, and lowering the efficiency of the machine. Incidentally, it may be mentioned that the bucking coil has been employed by firms in the United Kingdom who have used permanent magnets in place of shunt-wound field magnets for the dynamo. The permanent magnet is a fairly good equivalent, under certain conditions, of the shunt-wound field magnet; it is not such a good method of construction, in the writer's opinion, but it was fairly worth trial. The use of the "bucking coil" would render a larger permanent magnet necessary, if the bucking coil was always in operation. The writer believes that the permanent magnet method of construction of the small lighting dynamos for motor cars has not survived; it would have another somewhat serious defect, the magnetism tends to be gradually lessened with time. Modern permanent magnets, in which tungsten is employed as an alloy, are very much better than the old-time permanent magnet; they take magnetism much better, and, what is of more importance, they hold it better; but they do lose something, some portion of their ability to project lines of force into the armature core with time; and that would mean a lowering of the pressure. Also, except in special cases, dynamos made with permanent field magnets usually have to be larger and heavier than those made with wrought iron or special magnet steel for the armature cores and containing cylinders.

The writer suggests that the bucking coil would answer very well indeed if it were brought into operation, when the pressure furnished by the dynamo was too great for the accumulator, say, to prevent overcharging, and if necessary to prevent the accumulator receiving 2½ volts per cell when it only required 2.2 volts. In the systems of train lighting by electricity, an overcharge preventer is nearly always provided, but it is usually worked by reducing the current flowing in the shunt-field coils. In one system, however, one of the earliest on the market, the bucking coil is only brought into operation under certain conditions, to prevent the rise of pressure after a certain figure is passed. The writer suggests that by placing the bucking coil under the control of an electro-magnet, in a manner similar to that employed for the charging current of the accumulator, it might be made to do useful service. Fig. 13 is a diagram showing the connections of the suggested arrangement; the electro-magnet shown would be energized by a shunt current from the dynamo, or the accumulator, in a similar manner to that of the automatic cut in and out switch; but it would be set to operate at a very much higher pressure than the automatic switch does; say, at 2.5 volts per cell, and it would then connect the bucking coil to the brushes, and to the accumulator, the current flowing round it neutralizing the proportion of lines of force required to keep the pressure down. By this method the efficiency of the dynamo would be increased, and the number of turns of the bucking coil required would probably be less; the working of the system should also be very much more efficient.

Reducing the Current Flowing in the Shunt Coils.

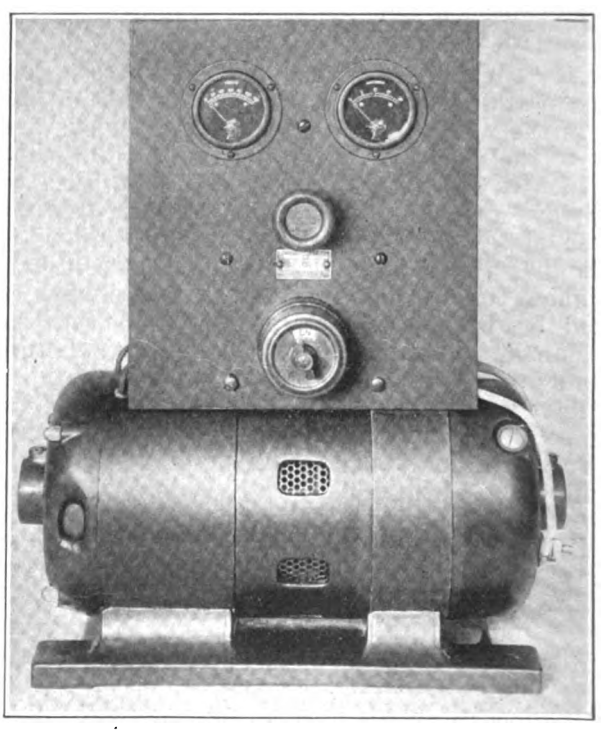
This is another method which is rather a favorite; one form of it was described in the Automobile

Digitized by Google

Dealer and Repairer of January, in connection with the North East Starting and Lighting System. In the early days of motor car lighting by electricity, another method employed was to throw in a resistance, into the circuit of the shunt field coils, by the aid of a centrifugal governor carried on the axle of the dynamo; the writer believes that that method has been given up, in common with that of regulating the voltage, by the aid of a slipping belt. It is perhaps interesting to note that the slipping belt is still employed in one of the systems of train lighting by electricity in the United Kingdom, the one that was earliest on the market, but that the bucking coil has been called into service to assist. Several of the systems of train lighting have methods of maintaining the pressure constant, by increasing and decreasing the resistance of the circuit of the field magnet coils. It will be understood that by inserting an artificial resistance in the circuit of the shunt field coils, the strength of the current flowing is reduced, and with it the magnetic pressure. Suppose, for instance, in the case given above, where the current in the shunt-field coils was 1 ampere, and the number of turns 1,000; if the current is reduced to 0.9 ampere, the magnetic pressure will be only 900 ampere turns; and if the speed has been increased 10 per cent., the pressure at the brushes should be maintained about normal. The working of a variable resistance, however, is exceedingly difficult, and particularly under the conditions ruling in a motor car, where the space is limited, and where it is not easy to arrange for the usual rheostat.

(To be continued.)

GARAGE AND REPAIR WORK.



Electric Power—The Current, the Fire Risk, the Voltage and Speed Control.

No. 3.

From J. F. Springer, New York.—The writer has already treated the gasoline engine and the steam engine. Both have their fields, which partly overlap and are partly outside of each other. There is a third type of power unit suitable for the shop. This is the electric motor. Naturally, it has its advantages and disadvantages, just as we found it to be the case with the others.

One of the advantages of the gasoline engine is possessed by the electric motor in a still higher degree. The gasoline engine need run only when its power is being used. So also with the electric motor. But since we may, if we choose, divide up the total electric power required amongst several units, we are able not only to limit the expense of power operation to the period when power is actually required, but we can go a step further and limit it to a small group of two or three machines or even to the one single machine it is desired to operate. This is a very considerable advantage, especially in a repair shop where only one or two machines are likely to be needed at a time. In brief, we use up current on the job and not on running the whole line shaft. This may be very important. Then, again, it may have but little importance. It depends upon the conditions in the particular shop.

What is sometimes a disadvantage in using electricity is the fact that the motor must have current supplied to it. If there is a central power station in the neighborhood, then this often becomes an advantage, for the reason that no fuel has to be handled at or near the shop. There is no boiler fire, no gasoline ignition. However, many shops may have difficulty of getting current at the time of day they want it. For example, there may be a municipal electric light plant which is willing to sell current, but only has it on tap at night. The conditions are then severe. In many cases, perhaps most, the thing to do is to turn to steam, gasoline or something else different from electricity. But there are still other cases, where electricity will probably on the whole seem the most desirable thing. The current obtainable at night may then be stored for daytime use. The storing of electric power or energy is the function of the electric storage battery. By means of this piece of apparatus we may utilize the energy at any time we choose; but naturally it costs something to get this privilege. That is to say, when we put one kilowatt-hour into a storage battery we are not to count on getting that much energy out. We put in so much, we get out a less amount. It may or may not pay to do it. That depends on circumstances. The shop may be so situated that the cost of power is not the chief item. It may be permissible to pay a good stiff price in order to secure the advantages. We must not get the idea that storage batteries are used only for small matters like the lighting of lamps on an automobile, etc. Storage batteries are used in part for supply-

Type MIC Form D 750 Watt Battery Charging Set with 110 Volts 60 Cycle Motor and 72 Volts Generator Complete with Switchboard Panel.

ing energy for operating railway trains in the tunnels beneath the Detroit River. One of the electric light companies in New York City has an enormous storage battery ready to go into service the moment a breakdown of the ordinary plant occurs. Street cars are run by storage batteries. So, it is no wildcat suggestion that storage batteries may be very

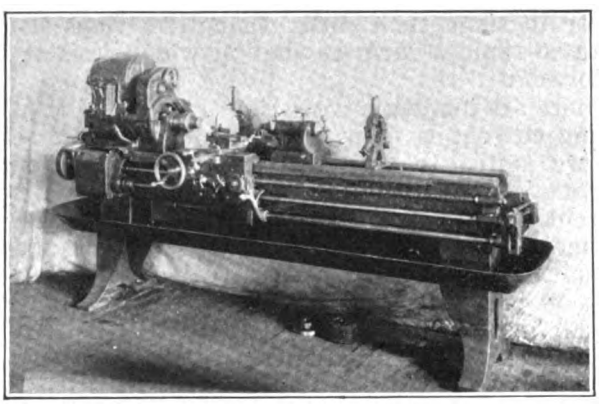
Digitized by Google

suitable for certain shop conditions. In considering the storage battery as a possibility, it should be borne in mind that we cannot employ alternating current when charging the battery. If alternating current is all that is available and a storage battery is to be used, then it is necessary to convert the alternating current into direct current. This may

Type KT-5 HP-1800 R.P.M.-440 Volt-3 Phase-60 Cycle Bd-2 Motor Driving Machine Shop of Main Cannery, Pacific American Fisheries, Bellingham, Wash.

be done by means of a mercury rectifier or a generator set.

In general, it will be best for the shop not to generate its own current. Ordinarily, it should buy current or use some other source of power. Usable current is of two kinds—direct and alternating. Motors are built, some to use the one, some to use the other.



While it is generally inadvisable to generate the current for a small shop, there are one or two classes of exceptions. Sometimes, it may be that a good deal of current will be used, partly in the shop and partly in other service. The shop owner may want electric light in his own home and may in addition have opportunity to sell current for light or other services to people nearby. It may then be an economical thing to have his own generating plant, consisting, say, of a gasoline or steam engine, a switchboard and a generator. If the plant is to be run at a different time from that when the current is to be used, then a storage battery must be added. If the total amount of current that is going to be used amounts to enough to require 30 or 40 or more horse-power hours of power per day from an engine to run the generator, then it may be well to look into the possibilities and costs of generating current.

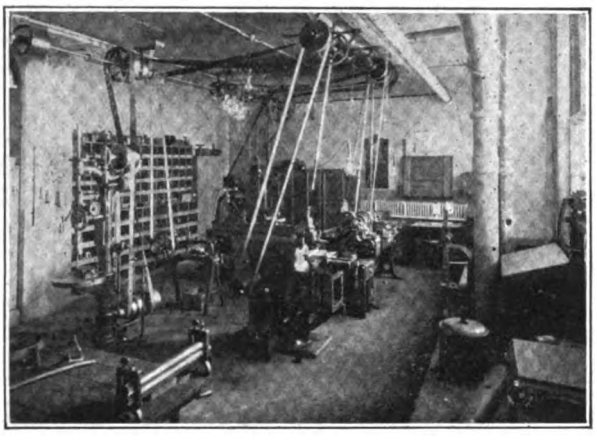
Before leaving the topic of the generation of one's own current, it will be well to have before us this caution: We should not adopt a low-voltage system unless the distance between generator and motor is short. The reason turns on the cost of transmission wire. If we were engaged only with the problem of running a few electric lights, we might easily do so with a 32-volt system. That is to say, if our generator produced current of this voltage, we should have a satisfactory way of running the lights, the distance of transmission being, say, not over 300 feet. If now we want to transmit energy enough to run turning lathes and the like, the wires will have to be greatly increased in size in case we use a 32-volt system. A higher voltage enables us to use moderate sizes of wire. Take an example: Suppose we want to transmit a total of 6 or 7 horse power. We can do it with a moderate size of wire, if we use a 100-volt current. If, on the other hand, we use the 32-volt current, this wire will have to have a cross-section nine times the area of the wire for the 100-volt current. If the distance is considerable, then nine times as much copper in one case as in the other means a serious item. However, a storage battery for the lower voltage would cost somewhat less than for the higher and thus create more or less of an offset.

As to the fire risk. Is there any substantial advantage favoring low voltage? It is claimed that there is not, the reason advanced being that the National Board of Fire Underwriters makes no distinction in their requirements as to wiring for 30-volt and 110-volt circuits.

A considerable argument in favor of the 110-volt system is that whatever equipment in the way of lamps, motors, etc., is employed is then standard equipment. If central station current becomes available later on, the change from the current from one's own generating plant to that from the station will be likely to be an easy one. Tungsten lamps for 110-volt current are now being made sufficiently rugged to meet the conditions on inter-urban street railway lines; so that one need have no fear of trouble because he sells 110-volt current to homes and stores.

Ordinarily, however, current will be bought. The thing that will have to be decided is whether a

Whitcomb Blaisdel 14" x 8' Lathe Driven by Type RL-53-1 HP 500/1500 RPM 250 Volt Motor



single motor is to operate the shop or whether smaller motors are to be used for individual machines and the like. The single motor is a very good thing, if the line shaft is not long and does not require much energy to rotate it. All we have to do then is to throw on the belt which will set the proper countershaft or proper machine in opera-

Digitized by Google

tion. There are cases, however, where it will be better to install a motor for each machine or each countershaft. The floor space of a motor is a small matter. Sometimes they are mounted on the machine itself and do not stand on the floor at all. At other times the motor will be attached at the wall or even the ceiling.

There are quite a number of advantages claimed for the electric motor. I mention the following: Few parts to get out of order; just two bearings to watch; constancy of speed as compared with the gasoline engine; there is no water to freeze; as readily started up in cold weather as in warm; weight per horse-power capacity very small; obtainable in very small sizes. Where individual motors are used, we eliminate a good deal of belting. There are no belts from line shaft to countershaft, nor from countershaft to machine. There may, however, be a belt from motor to a drive pulley, depending upon the particular arrangements. In fact, a belt is not a bad thing to have somewhere. In case of an overload on the machine, the belt can slip. This may avoid breakage of cogs.

The fact that a motor naturally generates its power in the form of a rapid rotation may often be

Type KT 3 HP-1800 RPM Motor in Machine Shop of Burnham and Morrill's Canning Plant, Portland, Maine.

advantageous. As a rule, the smaller machines want power in some such form, though perhaps not in quite so rapid a form as that in which it is in the motor shaft.

There are numerous varieties of motors. If alternating current is to be used, then one must select motors suited to this type of current. If direct current is available, then one may choose a direct-current shunt-wound motor. This variety has the commendation of Professors F. B. Crocker and M. Arendt of Columbia University. They state in their book on electric motors in effect that the conditions of the individual machine tool is best met by a direct-current shunt motor, since the speed of such a motor may readily be controlled.

Speed control is an important matter, since in a turning lathe, for example, one should vary the speed as the cut being made gets closer and closer to the axis of the spindle. That is to say, as we cut more and more towards the center, it is permissible to rotate the spindle faster and faster, since the amount of metal removed in a circuit is getting less and less. With the feeds the same, we cut off just about half as much metal in a turn when we are half-way in from the circumference to the center as we do when cutting at the circumference. We shall be wasting time and opportunity if we neglect this fact. By properly increasing the speed we can keep the lathe up to its duty.

There is, however, another way of getting the lathe spindle to rotate faster. We may do this without changing the speed of the electric motor. That is to say, we may provide for the change, just as we do in the case where we use line shaft and countershaft, by means of the cone pulley and also by means of back gearing. We may, in fact, use the motor to operate the countershaft instead of the machine; or we may drive the machine through the agency of a gear box and thus get speed variations.

A word or two as to safety. Of course, the wiring and everything connected with the transmission of the current should be done in the most approved manner. As to just what is such a manner, one can depend very well upon the regulations imposed by the National Board of Fire Underwriters. These regulations represent what the fire insurance people think—that is, what they think in so far as fire hazard is concerned. While they are presumably not gotten up with a view to preventing personal injuries, still when liability to fire is provided for, we have at the same time a good deal of protection for people as well. But this is not enough. Note, then, in the case of a motor whose purchase is contemplated, whether the operator and other persons will be protected against the current. Raise this question, and do not be convinced unless good and clear reasons are set forth. We are living in a day when safety devices of all kinds and descriptions are in successful use. It is much better to prevent trouble than to try to cure it after it has occurred.

(To be continued.)

THE HIGH COST OF AUTOING.

It Will Be Largely Found in the Scattering of Junk and Bolts on Road and Street.

From H. C. Brokaw, Principal Y. M. C. A. Automobile School, New York.—If some of the auto owners and chauffeurs do not mend their ways, some of the city streets will be paved with a mixture of asphalt and auto parts. If you do not believe this, look at the pavement on the busiest streets and see what a collection of junk you will find strewn along, particularly at corners where many cars make sudden stops.

To illustrate, the other day I noticed a car stop and the driver wondered what was the matter that the engine had no power. He happened to be near a garage and called for a mechanic to look at the engine.

"A few minutes ago," he said, "the engine had so much power I couldn't stop it when I wanted to, and now I can't make it pull at all."

When the mechanic had given it a "once over" he said to the driver:

"Open your throttle."

"The throttle is open," was the response.

"Oh, I see," said the workman, and he went back to the garage, hunted up a small bolt with which he connected up the throttle linkage so that the lever and accelerator pedal would open the throttle when

Digitized by Google

moved. What had happened was that through neglect the bolt had worked loose and dropped out, so that the lever did not move the throttle arm and advancing the lever had no effect.

The bolt probably is one of those to be found imbedded in the pavement somewhere about the city. An examination of the pavement of any of the automobile thoroughfares will reveal nearly all the 57 varieties of auto accessory parts in the asphalt. A great many of the bits of metal found there will be broken skid chain links, but I counted 26 different species of other lost parts in crossing Fifty-seventh street at Eighth avenue.

While I was counting them a driver came along and was unable to stop his car properly—the brake did not work and he had to use the emergency brake after nearly running over a pedestrian. He got out and found that a pin was gone in the brake linkage. A spring cotter had worked out or sheared off and the pin had rattled loose and dropped out.

Many of the stray parts are of a similar nature, nuts, bolts, washers, screws, cotter pins and the like which have worked loose because of neglect. Their absence will account, doubtless, for a good many of the rattles and squeaks which their former owner is now complaining of, and to replace which he will pay the garage man several times their value.

I have seen the pin holding in place the tie rod which keeps the wheels in alignment drop out, and in another case, hunting a knock found the cylinder loose on the base because the nuts had been without lock washers or cotter pins and had worked loose. They might, in time, have worked off entirely and then there would have been a "cylinder missing" for sure. I have also seen the entire engine loose on the frame so that it was doing a fox trot while being run.

The average instruction book given with a car will advise the owner to go over the car every so often and tighten up the bolts and nuts as a precautionary measure, but usually no attention is paid to this until the car stops or develops some unusual sound. Then a mechanic is called in and it takes him a couple of hours to find the cause of the trouble, while the owner stands around cussing the maker of the car.

Probably a good many of these parts along the road are due to careless mechanics who drop small parts in the dust pan and will not take the trouble to fish them out, or leave them on the running board and after a time they jar off to the street; but it shows there is a lot of carelessness among drivers when they even lose number plates and hub caps. I have a pair of brass hub caps picked up along the road which I have turned into ash trays.

The loss of hub caps allows grit to get into the bearings, and to prevent this as far as possible by making the driver take care of them, the manufacturers have made the prices of these parts entirely out of proportion to their real value.

Some of these lost parts are of such shape that they would very readily puncture a tire, so that they are not only a loss to the owner of the car from which they are dropped, but the fellow who follows picks them up for a punctured tire.

The owner should become so well acquainted with his car that he knows where the different bolts and nuts are. Many will tighten up all they know about, but do not bend their backs to get underneath where they can see the dust pan bolts and brake linkage bolts. If the owner knows where these parts are he should make it his business to see that every bolt and pin is locked with a lock washer or cotter pin. Then he should go over them at least once a month and tighten them up. He may be sure he will pay several times their value and a mechanic's time if they are lost, so that economy is involved as well as the inconvenience of having the car stopped on the road.

FUEL AND THE DRIVER.

How to Run the Car With the Least Possible Consumption of Gasoline.

F. C. Mock at the Midwest Section Meeting of the S. A. E.—It has been suggested that this paper discuss the subject from the standpoint of the carburetor engineer. It has been a peculiar development of automobile use that the carburetor builder is held continuously and directly responsible for the performance of his product, on whatever car it is placed, and his viewpoint is therefore closely that of the car owner. And since the ordinary driver's requirements of car performance are sometimes different from those of the automobile designer, a consideration from the former's viewpoint should be of definite value.

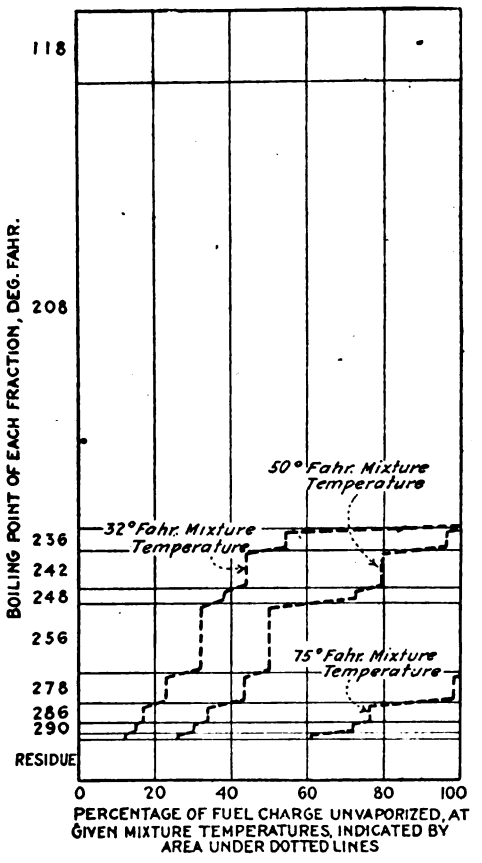


Fig. 1—Composition of 72-deg. B. "Straight" gasoline, paraffin base—from Pennsylvania District.

In the relatively short time of development of the automobile there have been many marked changes in the fuel use. In the early days, from 1902 to 1905, there was no fuel problem; gasoline was a by-product and so volatile that it only required proper metering with air to give efficient performance; with a normal running mixture the engines would start, cold, on the second or third half turn of the crank.

Digitized by Google

It was about 1907 that we began to have some difficulty starting with the hand crank, and to find it necessary to make the mixture adjustment a little richer for easy starting. A short while later we began to notice that an engine would not run quite the same cold as it would after it warmed up a bit. About 1909 it began to be evident that there was something in the engine that seemed to demand a graduation of the mixture. Power and flexibility seemed to demand more gasoline in the mixture than was necessary simply to keep the engine running smoothly. We began at this time to have definitely more trouble with carbon in the cylinders. There was not much difficulty with intake manifold design until we commenced to use more than four cylinders. About this time it became common to water-jacket the carburetors.

By 1912 the fuel had grown so much heavier that the self-starter was a necessary feature. Practically all carburetors were fitted with some special device for giving a richer mixture for starting. Although the carburetor makers had now practically solved the problem of producing a uniform mixture it was found that this was by no means sufficient to make the engine run, and they began to develop devices for graduating the mixture according to the evaporating conditions in the intake manifold. For instance, means of making the high speed mixture richer than the low speed by the use of separate adjustments and of devices for giving more gasoline on acceleration. At this time we began to have marked difficulty in making the cars run properly in the winter time. We felt that this difficulty was not due to a defect in the carburetor, although the public generally did not agree with us.

The fuel conditions during 1915 and 1916 are recent in our memory. About this time the gasoline began to contain elements boiling above 350 deg. F. and nearly everyone commenced to have trouble with gasoline getting into the crankcase, thinning out the lubricating oil and cutting the bearings. These years also marked the beginning of a period when the automobiling public and automobile engineers generally began to appreciate the difficulties under which the carburetor men had been working. The importance of this subject became more fully appreciated and in the last few months there has been a great deal of improvement in the design of intake systems. Practically all new intake manifolds are hot-water jacketed or have the exhaust heat on some portions of their surface, while practically all carburetor installations provide for a warm air supply.

Unfortunately these improvements are difficult to apply to engines already built, and many cars four or five years old, in the best of shape mechanically, are unusable through six months of the year because they cannot handle the present fuel.

The fuel situation in the country as a whole is further confused because of the variation in quality. In some localities the gasoline is as good as that used say in Chicago fourteen years ago; in other places it is similar to that used there ten years ago. The variation is so great that one single design of fuel intake system can rarely give good operation in all parts of the country.

Essential Properties of Automobile Fuel.

These differences in operation are not due to any deficiency in thermal energy, because all these gasolines have nearly the same calorific value, but rather to a deficiency in volatility, which interferes with the method by which they are delivered to the firing chamber of the engine.

The force that drives the pistons of our engines is derived from the combustion of the oxygen of the air charge in combination with hydrocarbon vapor

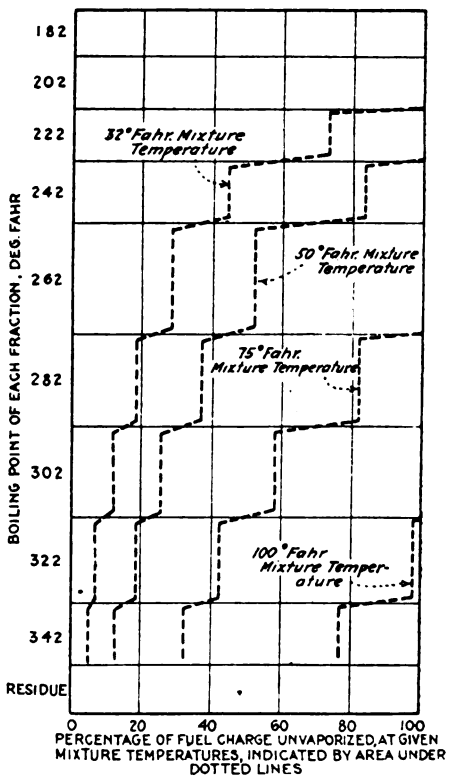

Fig. 2—Composition of 56-deg. B. gasoline used in mid-west auto section. Mainly paraffin base.

generated from the gasoline. The air is drawn into the cylinders by the suction stroke of the piston, from a common passage or manifold, while the gasoline is sprayed into this incoming air, at a chamber at the manifold entrance, which chamber we call the carburetor. Such parts of the gasoline as are sufficiently volatile evaporate into vapor and enter the cylinder along with the air. These volatile parts composed about 100 per cent. of the early gasoline, but this percentage has diminished until now, with our Mid-West fuels, only about 40 per cent. can be evaporated under the average operating temperatures.

The disposition of the unevaporated part of the gasoline depends on the velocity of the air carrying it, also upon the nature of the path along which the air must travel and, to a slight degree, upon the fineness of atomization of the gasoline drops. When the drops are small and the air velocity is about 20 feet per second, they are carried in suspension along with the air so that the effect is practically the same as if the gasoline were evaporated. When the velocity is lower than this, it is much easier for the drops to fall out. This collection or condensation is facilitated when there is a tee-bend or elbow in the manifold; the gasoline particles naturally proceed in their initial direction of motion until forcibly deflected from it by the wall on which they strike. As soon as the drops strike the wetter wall they are subject to surface tension and from then on they

Digitized by Google

cling to the wall of the intake manifold and pass along in a stream. If the air velocity at the bend is sufficiently high, about 50 feet per second, it will wipe much of this liquid part off the walls again and carry it along with the air.

Whenever the gasoline is carried in suspension with the air, it is easy to get good operation with any of our gasoline fuels. When the gasoline is not carried by the air we have trouble. For engines that run at a constant speed it is easy to design the intake manifold to have the requisite air velocity at that speed. With an automobile engine, however, the air velocity at the highest speed is about twenty times that at idling speed, and it is impossible to select an intake manifold size that will be equally efficient under all conditions.

What Gasoline Actually Is.

"Gasoline" is not a liquid of fixed and inflexible composition such as water or benzol, but is more nearly a trade name applied to whatever components obtained in the refinement of crude petroleum as are deemed possible to use as an automobile fuel. The crude petroleums obtained in different parts of the world are greatly different and this difference extends to the composition of the gasoline derived from them. When the heavier products are "cracked" to make lighter ones, still further variety is found. All these, however, are capable to complete combustion in an automobile engine if properly vaporized, and further have nearly the same number of heat units per pound.

On account of the extreme difficulty of accurate chemical analysis it is common to judge the composition of these fuels by the process of progressive distillation. A measured quantity of the gasoline to be tested is put into a flask and heated. As the temperature rises a point is reached when the liquid begins to boil. The boiling continues, with nearly stationary temperature, until all of the elements that boil at that temperature have been converted into vapor, which is conducted away from the flask and collected in a condenser where the quantity can be measured. If the temperature is then raised another boiling point will be found and another portion distilled off, and so on.

Figs. 1, 2 and 3 show the proportions distilled off at different temperatures in three samples, which are typical of the fuel commonly used in different sections of this country. The diagrams have been made in such a form that they can be conceived as representing what would happen in a barrel of gasoline if it were possible to separate the elements according to gravity. The lighter elements are at the top, the lower ones at the bottom and the included area represents the relative volume of each present. It will be noticed that the Eastern gasoline and the Mid-West gasoline are quite closely graded as to the percentage of each element present, while the Western gasoline contains an extremely large percentage of the element that boils at about 280 deg. F.

The exact boiling point and the exact proportion boiling off at each temperature are difficult to measure, because the values obtained vary greatly according to the speed with which the distillation is conducted and the nature of the apparatus. In making these distillations we endeavored to rise from one boiling point to another as quickly as possible, but held the boiling points.

A carburetor adjusted for Mid-West gasoline will operate very satisfactorily with 72 deg. Eastern gasoline. For some reason the Western gasoline (I understand that the Texas and South-Western gasoline is about the same as this) does not operate nearly as well and requires an entirely different carburetor adjustment.

The percentage of gasoline evaporated and its rate of evaporation further depend greatly upon the position of the throttle, or, more specifically, vary closely with the vacuum in the intake manifold.

Vapor Tension Apparatus.

Fig. 4 shows an apparatus of the kind commonly used to demonstrate vapor tensions, consisting of three glass tubes connected to a common mercury vessel. The upper ends of the tubes are sealed, and contain nothing above the mercury but liquid gasoline and vapor. In one tube is shown the 208 deg. F. fraction obtained from the California gasoline whose distillation fractions are shown in Fig. 3. The second tube shows the 342 deg. F. fraction taken from our Mid-West gasoline, while the third tube contains common kerosene.

If this gasoline or kerosene were not present, these tubes would be simply barometers and would

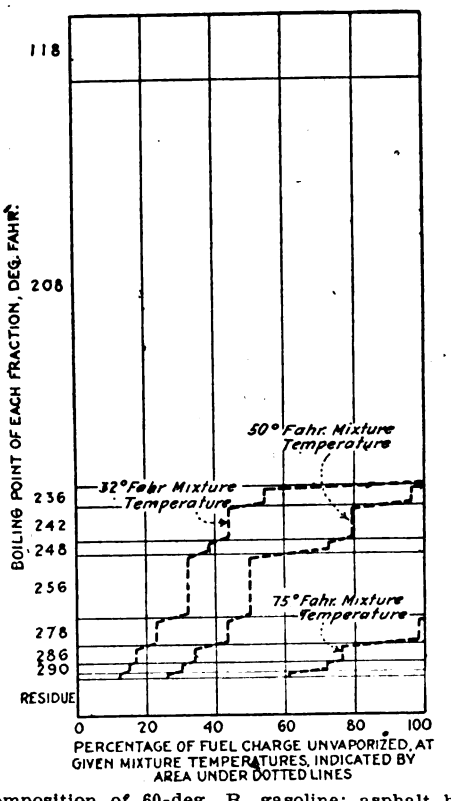

Fig. 3—Composition of 60-deg. B. gasoline; asphalt base, from California District.

remain absolutely full of mercury until the level of the mercury in the vessel was lowered more than 29½ inches below the top of the tube. If the vessel was lowered further than this the mercury would follow the lowering of the vessel to show the atmospheric pressure in this room, and there would be an absolute vacuum above the mercury.

The space that now exists above the mercury in the tubes is filled by a small portion of liquid gasoline and by the gasoline or kerosene vapor from it. The space occupied by the vapor of the 208 deg. fraction is about three times as great as that occupied by the kerosene vapor, while the space

Digitized by Google

occupied by the 342 deg. fraction is about 20 per cent. greater than that occupied by the kerosene vapor; this indicates the great difference in vapor pressure and density that accompanies the difference in boiling point of the gasoline elements.

The heating of the upper part of the tubes to a temperature of about 120 deg. F. causes the space occupied by each vapor to increase to nearly twice that occupied at the room temperature of about 72 deg. With this increase the amount of liquid gasoline above the mercury will decrease perceptibly, showing that more has been evaporated.

Factors in Evaporation.

There are two very important points that can be shown with this apparatus. As the mercury vessel is raised and lowered, the level in the tubes keeps the same distance above the level in the vessel; but although the vapor pressure or tension remains the same when the mercury is lowered to give more space in the tube, the amount of vapor increases with the volume of this space. This is shown by the decrease in quantity of liquid gasoline standing above the mercury column. For instance, if the mercury is lowered until a 12-inch space is shown in the 208 deg. gasoline tube, the liquid gasoline evaporates altogether. This corresponds to the change of conditions that we have in our intake manifolds when the throttle is opened. At any given engine speed, as we close the throttle we feed less gasoline, but we leave the same space for the vapor to occupy, with the result that a much greater percentage of the gasoline can be converted into vapor during the closed-throttle condition. This fact, in conjunction with the preceding ones, gives the reason why we have difficulty in handling our present-day heavy fuels at wide-open throttle and low air-velocity.

The second point of importance is that when the mercury is lowered to allow room for the increased evaporation, the change in state occurs at once. Within a second the gasoline evaporates to fill the space available. This shows, what we have believed from experience, that the predominating factors in determining the actual evaporation of gasoline in the intake manifold are the vapor tension of the various elements and the temperature, and that we do not have to allow time for the gasoline to evaporate; in other words, the gasoline evoprates, as much as it can, almost immediately upon passing the throttle.

In recent years we have helped engine operation by preheating the air charge or by heating the intake manifold, but the heavy elements introduced into the gasoline lately are so non-volatile that their complete evaporation requires heating the manifold and entering air above the boiling point of water, and to so high a temperature that the amount of air charge, and consequently the power of the engine, is perceptibly reduced.

In some recent experiments we directed an atomized supply of gasoline into a bent elbow, through which air was being drawn, and noted the condition of the issuing mixture when the elbow was heated at different temperatures. Although the spray was very fine indeed, so that it would change into a mist and then disappear when the jet was directed into the air of the room, in the elbow the action was very bad. The gasoline would strike on the far wall of the bend and drain back out of the elbow in a steady stream, while only a few particles would issue from the mouth of the elbow. This was at temperatures of the elbow from 70 to about 220 deg., with the entering air at about 70 deg. When the elbow was heated to about 250 deg. conditions were better. With engines of the present design we can almost use satisfactorily our better Mid-West gasoline, provided we make a few practical allowances. It is possible that we can develop further our engine and thus allow us to use still heavier fuels. I am sure however that we cannot use heavier fuels than the engine will stand without great trouble in average use. For instance, a great deal of gasoline sold contains a perceptible amount of kerosene. With the average carburetor on the average car one to three years old, the driver would be much better off, get better service and equal mileage for his money if after buying this gasoline he could separate, remove and throw away this kerosene fraction. It does no good and does do harm.

In the face of conditions such as I have described, it is impossible to set any definite limit or requirement for gasoline standards. I believe however that if we adopt any convenient standard of graduation, the situation will solve itself on an economic basis, as each automobilist will buy the cheapest grade of fuel that he can use. When he buys a new car he will naturally select one that will handle the heavier fuels. This will make it a definite object for the car manufacturer to use a heavier fuel and will promote this development faster than any other way.

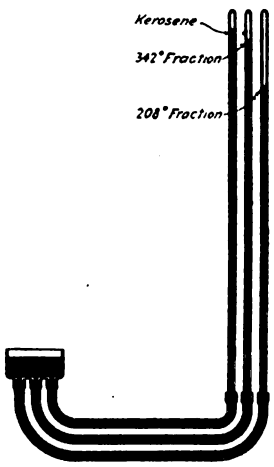

Fig. 4—Demonstrating vapor tension.

Use of Heavier Fuels.

Until a very short time ago we had not seen in operation any system that would use kerosene without there being so many disadvantages that it gave no promise for automobile use. In fact, kerosene is scarcely satisfactory even on engines running at constant speed, where there is no limitation as to intake air velocity or as to the amount of heat available. We have recently found by following a cycle whereby the kerosene is vaporized at a very high temperature, and then mixed with a charge of air at low temperature, that the resulting fog can be kept in complete suspension in the air stream. This should do away with the troubles previously described, so far as they relate to conduction of the fuel to the cylinders. There remains the further difficulty of obtaining a vapor in the cylinders, so

Digitized by Google

that the spark can be carried away from the spark-plug points. Such trouble can probably be overcome by mixing the kerosene with some of the elements now found in gasoline: this is also desirable as a step toward economical use of our fuel resources, because such a blend corresponds more nearly with the composition of the natural petroleum product.

AMONG INDIANA SHOPS.

Welding a Big Gear Wheel and How to Take Care of Expansion and Contraction.

BY JAMES F. HOBART, M. E.

The garage man seems fast becoming a village "Citizen Fixit" and all sorts of jobs find their way to his shop, particularly if he has an oxy-acetylene welding outfit. Recently I sat in a nice little automobile repair shop and saw a farmer bring in a piece of a windmill pump to be welded. Another farmer fetched a broken chain, bringing it to the welder instead of to the blacksmith next door. The farmer wanted a broken link closed. The garage man did it in four minutes. The smith would have been forced to throw away the broken link and make a new one which contained sufficient metal to make up for the waste in welding.

Before the farmer had gotten away with his mended chain, a team drove up with a big cast steel gear, 48 inches in diameter, with a big hub bored for a four-inch shaft (3 15/16 inches, to be exact) which had been broken in one of its arms, close to the hub as indicated at A in the illustration. The gear weighed several hundred pounds and was a load for two men to handle. A fall of about 15 feet had broken the arm and had also badly bent the rim of the gear. So badly in fact that the garage man was unable to straighten the rim and had to send the gear to a neighboring machine shop where it was heated and the rim straightened under a steam hammer.

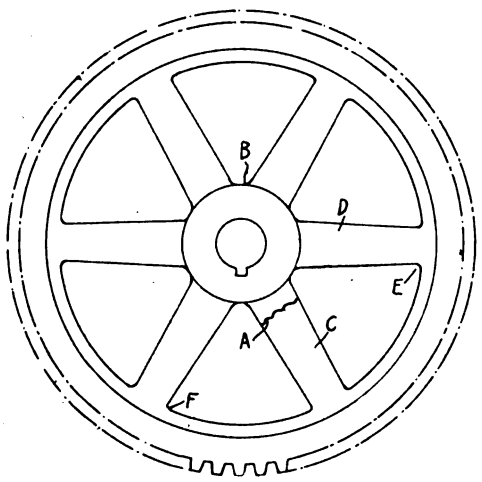
The garage man had in the shop a large portable forge, the cast iron top of which was a little more than four feet across, and upon this forge the straightened gear was placed for preheating before the welding operation was commenced. The broken spot was placed directly above the fire and coal was piled in and around the hub until the latter was well covered. The preheating was commenced in the early morning as soon as the shop was opened for the day and the heating was continued until about three o'clock in the afternoon, when the welding was done. The bends in the rim were at E and F, and these being satisfactorily straightened, no further attention was paid to the rim, but the preheating was all done between C and B, the parts A and B being red hot when the welding was commenced. In order to make the heating more even, pieces of sheet iron were placed underneath the gear wherever it projected beyond the edges of the forge and forge dirt and ashes were spread liberally over the pieces of iron so as to better hold the heat of the fire. Pieces of asbestos board about ¼ inch thick were placed on top of the gear and then other pieces of sheet iron were placed over the asbestos, closing in the gear so well that not much heat was wasted by radiation. The fire was handled well. Every few minutes the blower would be given a few turns, brightening the fire, after which it would be let alone for a time, then another turn of the blower would be given. In this manner the fire was kept going all the morning and the gear hub and roots of the arms were heated very slowly and evenly until a deep red was reached, when the welding was done, the flame of the torch being used to cut away the corners of the break. This was done by the welder in preference to chipping the corners off of the broken edges.

The writer, who heretofore had been a silent onlooker, visiting the garage several times during the forenoon while the heating was in process, now took the garage man one side and quietly made a very strong protest to him in regard to the manner in which the preheating was being done.

"What the h—— do you know about it?" was the reply made by the garage man, who went ahead, welded the gear with the hub preheated as described. Then he replaced the gear upon the forge, covered it carefully with the sheet iron and asbestos, and also placed a lot of dry dirt on top of the sheet iron in order that the gear might be a very long time in cooling.

In the morning, when the team came for the gear, the garage man uncovered it preparatory to loading it upon the customer's wagon, and there was the crack again, at A, same as it was before the welding had been done! The garage man thought he knew how to weld a gear, and he did know how to perform the actual welding operation, but he did not know how to take care of contraction and expansion, and these were the forces which pulled the arm apart again at A.

After this, the garage man really did some thinking, and began to realize the fact that what the writer knew about welding a gear might be something after all. This matter exemplifies the saying of the old man who said "The boy thinks the old man is a fool, but the old man knows the boy is one." The garage man then replaced the gear upon the forge, heated the broken part of the arm at A, heating along the arm at C, and into the hub as little as was possible and have break A well heated. Then the rim was heated at E and at F, a couple of big kerosene blow torches being used for heating those portions of the gear rim.



The heating of the rim was pushed until the crack at A opened to twice its width and the rim heating was kept up during all the time of welding. In order to make the blow torches have better effect, the rim at E and F was covered with bits of wood—pieces of board—and the blast from the torches directed upon the metal through openings between the pieces of board. The wood surfaces were soon charred, then actually converted into charcoal, which, becoming ignited and glowing hot, caused the rim to be heated much better and quicker than was possible with the blow-torches without the wood.

The object of heating the rim until break A was open double its width while cold was to take care of the expansion and contraction of the heated metal at the break, also of the expansion caused by preheating the hub and the arm at C, something necessary but not at all desirable. This job could have been done without preheating the hub and arm C at all, and by doing it in that manner would require less heating at E and at F, but would require a greater expenditure of gas, both of oxygen and of acetylene for the reason that much of the heat

Digitized by Google

applied to break A by the welding torch, would have been absorbed by the cold metal on either side of the break. Preheating the hub and arm C lessened the gas consumption and that's about all it did, save perhaps to lessen the possibility of a "cold-shut" in the middle of the weld where the welder perhaps would have failed to let the jet of gas play long enough to melt the cold metal clear down to the very middle of the arm-section. To be sure, preheating the broken place is always desirable, but bear well in mind that the more heating that is done to hub and arms, the more expansion must be given to the rim at E and F in order to take care of the contraction which is coming to both the weld and to the preheated hub.

It is not always easy to tell how much the arm of a gear or of a pulley will contract after it has been welded, and good judgment, backed by experience, is necessary to give the welder a knowledge of how much any broken part should be preheated. There is not much danger of preheating the rim too much. If that should be done, however, the result would be to make the gear slightly eccentric

Broken 48-inch gear wheel.

—oval in fact—but it would not cause the rim to break because the contraction there cannot exert a direct pull upon any piece of metal as is done when arm C is welded and grows shorter as it cools. Were the rim to be heated too much and crack A opened more than the amount it would close during the cooling, then the rim at E and F would simply bend a very little and arm C would be left a very little too long, forming a bunch or a high spot in the rim of the gear, and that would be all the ill effect caused by heating the rim too much at E and B. But, as stated, there is very little danger of thus heating the rim too much, so no one need worry over that matter.

The garage man in doing this job of welding—and, by the way, the second time he welded the gear, after following the writer's instructions about heating the rim, the weld did not break—did a whole lot of unnecessary work in preheating precautions, also in cooling the gear again after the welding had been finished. The covering of the gear with sheet iron, asbestos and dry dirt after the first welding was absolutely of no use and did not a particle of good. It is not always necessary to cool welded parts slowly. Sometimes, and usually, they may be allowed to cool quickly and naturally in air, but sometimes it is necessary to cover the weld so it will cool slowly while the preheated parts are better if cooled as quickly as can be done with safety. Again, it is sometimes necessary to hold back the cooling of the parts heated for expansion, while the weld may be allowed to cool quickly.

In fact, the whole thing comes down to this: Cool both the weld and the expanded parts, A and E F, Fig. 1, according to their thickness. If both parts are of the same section thickness, and would cool equally fast, then there is no benefit whatever to be derived from covering the parts with hot sand or ashes, or of packing the article in dry lime to cool slowly over night.

But whenever one of the two parts is very heavy and the other very light, it may be necessary to cover the thin section in order to keep it hot longer so that it may become cooled in the same time that the thick portion requires to lose its heat. In case of the gear shown by Fig. 1. There is no sense or reason in covering the hub and arm C in order that the cooling may be slow. In this case it would have been better to cover the rim at E and at F in order that the comparatively thin rim section might hold its heat longer and cool in exactly the same length of time required by the thick hub to get rid of its heat.

Welded or preheated parts should never be cooled with water, unless in case of a hardened tool. Neither should the heated parts be exposed to heavy drafts of air, but both the weld and the expanded parts may be cooled as quickly as normal air temperatures can take away the heat with no danger, provided both the weld and the expand be cooled in the same length of time. That is the one thing to be watched. Cool each in the same length of time and the weld will hold, be that time one hour or one week.

Another welding fallacy is that it is necessary to be all day in heating or preheating an object which is to be welded. It is only necessary to give time enough for the heat to properly diffuse itself through the mass to be heated. Heat travels at a pretty good rate of speed through a large mass of iron. It is only necessary to take time enough so that the parts to be welded are uniformly heated, and that is usually a matter of minutes rather than of hours, therefore it is probably only once in a hundred jobs that half a day or more is necessary to be spent in preheating.

Using Too Small a Tip.

The welder who has never worked upon large pieces of metal, usually makes the mistake of using too small a tip, thereby thinking to save a little gas which otherwise would be wasted by using a large tip which consumes more gas than the smaller one. But often it will be found that far more gas is required to do a given amount of welding with a small tip than with a larger one.

The reason for this seeming paradox is that with the small tip the welding flame is necessarily smaller and far less powerful than with the larger tip and the mass of metal being large, conducts away heat nearly as fast as the small tip can supply it, thus making the welding operation occupy so long a time that more gas is actually consumed than would be

Digitized by Google

required to operate a larger tip for the shorter time necessary to make the weld with the larger tip.

This matter of the size of tip to use is a matter which must be decided by actual experience, by trial and by the use of horse sense on the part of the welder. Doing a good many jobs is one way of obtaining this experience, but there is another way of acquiring the necessary knowledge and that way is by means of a number of trial welds. Procure some iron bars, either iron or steel will answer, and cast iron is as good as anything. Let the bars be all the same size and shape. Place two bars with their ends in contact and weld them with a certain size of tip, taking the time necessary to make the weld and noting the actual gas consumption.

Before proceeding to the actual welding operation, make up some "pills" of beeswax, tallow or some similar substance which will melt readily at a low temperature. Place a row of these "pills" upon the bars an inch apart in either direction from the place to be welded, and after each weld is made with the different size of tip, note how many of the "pills" have been melted on either side of the weld.

The above tests will enable the inexperienced welder to form a pretty good idea of the proper size of tip to use for any weld he has to make. Particularly will this be so if the above noted experiments be carried out upon bars of various sections in order that the heating and time effect may be compared both with regards length of time and size of masses welded as well.

After the welder has repaired several pulleys and gears, he will have observed that those with curved arms were not as apt to break through careless handling as regards contraction than were those with straight arms similar to the gear shown by Fig. 1. This is a fact, and it was for the purpose of taking care of contraction stresses while the gear or pulley was cooling in the foundry that caused curved arms to be first used in pulleys or gears. A foundryman observed that the arms in certain gears and pulleys almost invariably broke, sometimes many, or even all the arms being sure to break. With other patterns, few or none of the arms broke and this led to the making of curved arms where the lack of proportion between the section of metal in hub, arm and rim, caused the arms to be pulled apart when the rim cooled first. With curved arms, the dead tensile pull is changed into a bend which the curved arm can stand without being actually pulled apart endwise.

But, Mr. Welder, whether the arms be curved or straight, just remember when you make a weld, that the stress is there just the same, and that it is right up to you to figure out where and how you must heat the rim in two or more places in order that its cooling may equalize the cooling of the weld and thus prevent the weld you make from being pulled apart by uncared for contraction.

A Big Automobile Order.

The Canadian Pacific Railway reports from Calgary, Alberta, that a Lethbridge automobile dealer has ordered a million dollars' worth of automobiles for the Southern Alberta trade, mostly farmers. Southern Alberta has had two immense crops and expects a record yield again this year, with the result that farmers are buying automobiles.

BALL BEARINGS.

Their Proper Construction, Operation, Care, and How They Should Be Fitted.

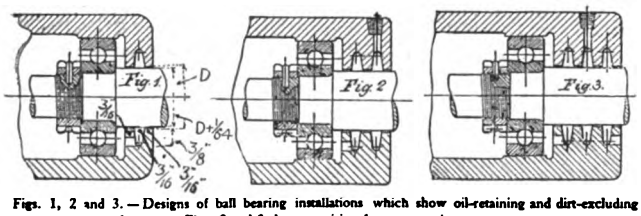
From H. Wickland, the Hess-Bright Mfg. Co., Philadelphia.—Grit and other foreign matter must be absolutely excluded from a ball bearing. Grit will quickly grind down a bearing at a rate depending upon the sharpness of the grit and the constancy of operation.

Grit may enter a bearing in various ways. After the bearing is taken out of its cardboard box it may lie around on a dirty bench and pick it up in this way. For this reason a bearing should never be taken out of its box until the shaft and housing are ready to receive it. If it is necessary to unpack it before this time, care should be taken to see that foreign matter does not work its way in. If the bearing should pick up foreign matter it can very readily be cleaned out by washing in clean kerosene. In many repair shops the can used for this purpose has also been used for cleaning gears and other parts, and often contains dirt and metallic particles. Attempting to clean a bearing in this will manifestly result in making the bearing dirtier.

The presence of small particles of grit in a bearing can be easily detected, since the bearing will run with a "catchy" or "sticking" motion; in other words, it will not run smoothly. The remedy is to spin the bearing in a bucket of clean kerosene, which will wash out the grit or other foreign matter.

Before a bearing is assembled in its housing, the housing should be absolutely clean. Those parts of castings not machined should be examined to see that no sand adheres. All turnings or borings should be carefully cleaned out. Tapped holes for grease or oil cups should not be tapped after the bearing is assembled in the housing, since the drillings and chips from the tapping operation will fall into the box and ultimately work into the bearing. This may seem like a warning against an improbable occurrence, but it has happened in a number of cases.

Foreign matter may be introduced into a bearing through the lubricant used. See that the lubricant is clean. Do not use greases containing foreign matter, such as mica, talcum, sawdust, ground cork, etc. All of these substances are injurious to ball bearings, since the balls must roll over the solid particles like a stone crusher, and as the running clearance between the balls and grooves is slight, injurious wedging is bound to result.



Finally, the housing may be of such a design as to admit foreign matter. Figs. 1, 2 and 3 show oil retaining and dirt excluding designs which have proven very satisfactory. In particularly dirty locations many constructors prefer to fill the grooves with felt packing or a stiff grease. This is desirable. Figs. 2 and 3 show provision for compression grease cups to keep one groove filled with a semi-solid grease that makes a definite, frictionless packing. In all cases the lips should have sharp edges and should be bored out not over 1/64 inch larger than the shaft.

A ball bearing must be of suitable capacity for the load, speed, and conditions of service under which it works. An overloaded bearing will not be worn in the ordinary sense of the word, but the surfaces

Digitized by Google

of the balls and grooves will be destroyed. This will show first by minute pin holes and later by flaking. A large ball will take more than its share of the load and may, therefore, bring about all the appearances of an overloaded bearing. To avoid this, no ball must vary more than 0.0001 inch from its fellows in the same bearing. It is on this account that bearings should never be dismembered by the user, since otherwise balls are likely to be mixed. Neither must remaking the bearing be attempted by adding balls to a set. Such remaking should be undertaken only by the bearing manufacturer where full sets of even size balls are available.

Rust is absolutely destructive to a ball bearing. It is very readily recognized. Even in a bearing which has been cleaned so that no red rust is to be seen, the presence of more or less pronounced pits and excoriations, not only on the race surfaces, but also on the other parts of the bearing, is clear evidence. These pits are very distinct in appearance from those due to overload; aside from that, overload pits are necessarily confined to the balls and

Figs. 1, 2 and 3.—Designs of ball bearing installations which show oil-retaining and dirt-excluding features. Figs. 2 and 3 show provision for compression grease cups

grooves. The remedy for rust trouble is to see that the housing is of such design as to prevent the entrance of water or moisture from any source whatever. If the operating conditions are such as to make it necessary to locate the bearing housing in a damp location, see that an excess of lubricant, enough to force out at the closure, is employed, and if the moisture is excessive provide a stuffing box design of cap for the housing.

Although to many the presence of acid or alkali in many lubricants is well known, its destructive effect is not generally conceded, but is attributed to rust and overload. Nevertheless it is a very serious menace with some lubricants. Its ravages are clearly enough distinguished from overload because they are found elsewhere than on the balls and grooves. The marks are also quite distinct from rust marks. The acid marks often are pits, but always show also clearly defined irregular etchings, similar to, though less pronounced, than those produced by acid etching of damascened gun barrels.

Do not use lubricants containing acid or alkali; use a neutral grease or oil. In the oils, free acid, or the possibility of its development, must be guarded against. Hence, vegetable and animal oils should never be used, since these become rancid and develop free acid with age. Mineral oil is the only satisfactory oil for ball bearing lubrication. In the greases, free alkali is to be guarded against, since its action is the same as that of an acid—to etch and pit the races and balls. Make certain that the grease you use is of neutral, chemical composition, that it does not whip out too thin in service, and that it is one that will not dry up appreciably over an extended period of time, since in many instances the bearings are only lubricated at intervals of from three to six months.

Distortion or pinching of the outer race may occur where the bearing is mounted in a split housing, although it can be brought about by mounting the bearing with the outer race tightly fitted in a housing out-of-round. A bearing which has been distorted or pinched in the mounting is easily recognized, since the outer race groove will show a widening out of the path of wear at two diametrically opposite points, these points, of course, being on the reduced diameter. If the distortion has been sufficient, flaking of the outer race grooves will show at these points, and flaking and breakage of balls, as well as breakage of the races can also occur.

The outer race of a ball bearing should have a neat slip fit, free from shake in the housing—what is termed a sucking fit. This fit will enable the race to have a slow intermittent creep under the slight vibrations of the load, and hence the wear in the outer race groove will be distributed all around the groove instead of being localized. It is absolutely necessary to make certain in any split housing job that the outer race has this sucking fit, since then it will be known with certainty that the bearing is not being distorted or pinched.

Tight fitting of the outer race will also result in noisy operation and undue wear in the race grooves. All bearings must have a certain running clearance—a bearing with too little running clearance will run with a "singing" noise. The inner race being a light drive fit on the shaft, uses up some of this running clearance between the balls and grooves, and if the outer race is also tightly fitted in its housing, the probabilities are that all of the running clearance will be used up with resultant noisy operation and undue wear.

The necessity for having the inner race of a ball bearing a light drive fit on the shaft, is generally understood. A reliance on a drive fit alone is not sufficient, as that may be destroyed by an occasional dismounting. Then, again, the fit of the inner race may be only on a few high points, particularly with soft shaft material and ordinary lathe or file polish fits. When such a condition exists, the continued action of the load, concentrated on the short shaft length corresponding to the bearing width, will tend to peen down the shaft and cause the bearing to become loose. In many cases, this results in a serious cutting of the shaft. The fact that an inner race has been a loose fit on the shaft is readily recognized by the highly polished condition of the bore. From the above it will be seen how necessary it is to have the inner race a light drive fit on the shaft and securely bound endwise between a substantial shoulder and a well-set-up nut with provision for locking. About the best way to explain how an angular bearing may be subjected to excessive end thrust is to give the fundamental mounting principles for two or more bearings on a shaft, and to show why these principles should not be disregarded.

When two or more bearings are used on a shaft, one bearing only, preferably that carrying the lightest load, should be used for locating the shaft endwise and carrying such thrust as is incident thereto. This bearing should have a clearance of 0.01 inches each side of its outer race with shoulders in the box. All of the other bearings on the same shaft should have ample clearance on both sides of the outer race, so that they can float endwise, assume their proper position, and carry nothing but radial load.

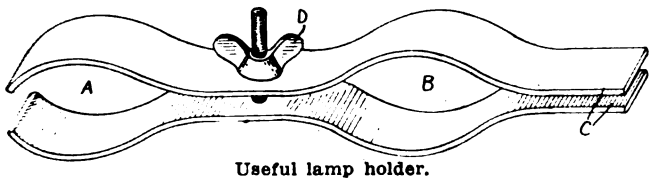
Reciprocal License Laws.



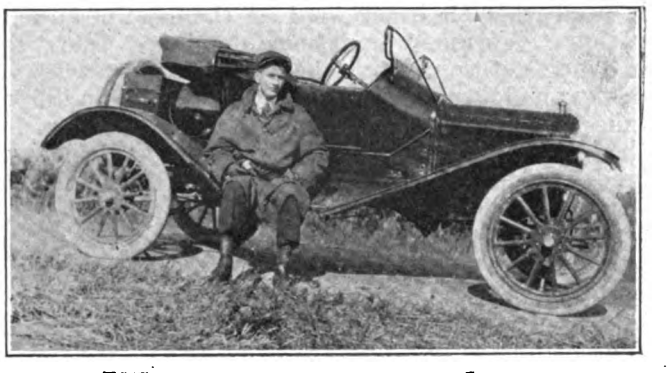
Automobile reciprocity between New Jersey and New York States was the subject of a conference recently between Francis Hugo, Secretary of State, and William L. Dill, Commissioner of Motor Vehicles, of New Jersey. To all who have been in the habit of motoring between these States the subject under discussion is a vital one. Mr. Hugo explained to Commissioner Dill that he was ready and willing to extend a longer reciprocal period than the fifteen days if it were possible for New Jersey to return the privilege.

It is realized, however, that the present fifteen-day reciprocal agreement between the two States must continue so long as there is a clause to that effect in the New Jersey statutes. While no immediate action could be taken, it was conceded by those present that the conference will have a beneficial effect in promoting better relations between the authorities in the neighboring States, who are charged with the enforcement of the motor vehicle laws. The idea is that each State should do its utmost in promoting pleasurable operation of all cars within its boundaries, consistent with the proper enforcement and observance of the laws of each.

A Trouble Lamp Holder.

In the illustration shown is a home-made holder for a trouble lamp or a flash light. It will be found a useful addition to the automobile equipment repair outfit.

When using this holder the main feature is that both hands are free, as the lamp or flash light is placed in the circular opening A, and the other circular opening B, is placed around the spoke of the wheel if such be the case or around the manifold when a repair is necessary. The flat ends C, are for



Useful lamp holder.

use in such cases when it is necessary to attach the lamp to the chassis frame or some other flat surface of the car when doing repair work. The holder is made of spring steel about ¾x3/32 inches, at the center between the two circular openings is a thumb nut D, to allow for adjustment. The holder can be bent and shaped over a piece of 1-inch pipe while held in the vise. The illustration is one-half the actual size.

A Remodelled Ford Car.

From H. C. Mertz, New York.—In your February issue Mr. Farrar of New Hampshire, shows a cut of his remodeling a 1910 touring car (Ford). I enclose herewith a photograph of my 1911 Ford roadster. The changes are as follows: 30x3½ tires all around, tank moved ahead 4 inches to suit case trunk on rear, capacity two cases, tire irons and tires on rear, top lowered 4 inches making a neat appearance when up. Cowl dash and doors, clear vision ventilating wind shield made of ⅞ gas piping, lengthened hood, bullet head lights fitted with dimmers, current from a six-sixty storage under seat, enlarged water capacity extension on inside and a rounded front holding 5 gallons instead of 3, this we find very efficient. Large steering wheel, foot accelerator, instrument dash with all light switches, speedometer and oil gauge. The car is fitted with shock absorbers (H and D),

Mr. Mertz and his Ford car.

Dann insert anti-rattlers throughout and a starter. The body is a deep wine color, also the wheels, while the fenders and gearing are black. This combination makes a neat job. I hope this will be of some benefit to readers and Ford roadster owners who wish to remodel their machines.

Speed and Comfort.

Disguise it as we may, to secure the utmost health, comfort, pleasure and economy in driving the speed should not be more than 15 or 18 miles an hour. Here are some remarks from an exchange that will be endorsed by all save the speed maniacs:

Tires last about twice as long on a car that is driven at 15 miles an hour as upon cars driven at 30 miles an hour. Speeding generates heat, which is an enemy to rubber.

Driving a car around a sharp corner at 25 miles an hour does more damage to the tires than 200 miles of straight road work. Excessive side pressure on tires may pinch the tubes, and it always strains the side walls of the casings.

High speeds are likely to cause skidding and breakage of springs and steering gear, any of which are dangerous when speeding.

In proportion to the mileage obtained, high speeds require more gasoline and oil than a moderate rate of traveling.

Driving a car at excessive speed, especially over rough roads, subjects the bearings to enormous strains.

High speed may cause crystallization of rapidly moving metal parts that are subject to strain and these may break at any time without warning.

High speeds interfere with the accuracy of steering, as is shown by the number of reckless drivers who have gone over banks and into ditches, especially on curves.

How Much Ford Makes.

The Ford Motor Company makes a profit of $21 on every car it sells. This was brought out by Vice-President Klingensmith, testifying in the Dodge-Ford suit. He stated that it cost the Ford company $260 to make a car; the price to the dealer is $281. He said further that the Ford company aims to earn 12.01 per cent. gross on $250,000,000 business in 1917.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

Lack of Road Attention.—In Utica, N. Y., one woman was killed, and two men and one woman injured when their car went off the edge of an excavation. Workmen had been employed there, but had not yet completed the repairs under way. A detour had been arranged, but this party did not take it, and went right ahead through a fence into the excavation. The car turned over twice and landed bottom side up at the foot of a 25-foot chasm.

Did Not "Stop, Look or Listen."—One man was killed and another probably fatally injured and two others slightly injured when a train struck an automobile in North Hampton, N. J. The party in the car was evidently entirely oblivious of the approaching train.

Result of Skidding.—Three men were killed and buried beneath an automobile wreck in Doylestown, Penna., when a car overturned owing to the bad condition of the road while undergoing repair. The car encountered mud, and skidded, and before the driver knew, it suddenly overturned.

Throttle Caught in His Sleeve.—In Lynn, Mass., a boy lost control of the car he was driving because his sleeve caught in the throttle in some way. The lad was thrown several feet into the air, and the car was badly wrecked when it struck the sidewalk.

A Deadly Grade Crossing.—Five persons were killed near Los Angeles, Cal., when a freight train demolished an automobile at a grade crossing. A row of trees shut out the outlook, and instead of stopping and making sure that the road was clear, the car was driven upon the track. It was a fearful tragedy, even the family cat, which was being carried in the car, having been killed.

Car Hit a Baby Carriage.—In Boston, Mass., a woman who was driving a car lost control and it struck a baby carriage after mounting the sidewalk. The child was tossed to the sidewalk and the baby carriage smashed to atoms, but no one else was especially hurt, although they were all very much frightened.

Crashed Through Stone Wall.—In Weston, Mass., a man was instantly killed and two women and three men injured when their automobile crashed through a stone wall and over a six-foot embankment into a ditch. The driver of the car was arrested on charges of manslaughter and drunkenness. He did not have a registration card. He apparently lost control of the car and the machine left the road at a sharp corner.

An Unskilled Driver.—In Salt Lake City, a boy was run down by an automobile while playing in the street. The car zigzagged, through a crowd of children, but one failed to get out of the way and he was dragged under its wheels. The driver stopped and picked the little boy up, but he was dead. He was a novice at driving, and says he did not realize how fast he was going.

This Happened After Dark.—A woman was killed on Long Island, N. Y., and a man injured in a collision with an unidentified car going in an opposite direction. The car that caused the accident sped on and disappeared in the darkness. The impact was so terrific that one woman was hurled several yards away, striking head-first on the macadam road.

A Pathetic Scene.—In New Orleans owing to the failure of a car driver to blow his signal horn a woman was run over and almost instantly killed. Her husband was near and threw himself across her prostrate form, kissing her again and again, and muttering a prayer.

While Inspecting the Rear Lamps.—In Philadelphia while a man was tinkering with the rear lamps his car suddenly backed up, and the man was jammed against the side of a trolley car. His skull was crushed, and his body otherwise mangled.

A Drinking Joy Ride.—One girl was killed and two others badly bruised at Tenafly, N. J., while they were riding with two men. The police are of the opinion that the party had been drinking, and the driver failed to notice where the street ended. The automobile was capsized and the driver has been committed to the county jail on a charge of manslaughter.

Due to a Slippery Pavement.—A woman was killed and her husband seriously injured at Napa, Cal., when the car in which they were driving skidded, and the driver lost control of it. It dashed into a wooden foot bridge, turned a complete somersault, and landed upside down in the bed of a creek.

Hit a Rut in the Road.—Near Pittsfield, Mass., a car struck a rut in the road and overturned. One person was killed and four were badly hurt, and hoists had to be used to the car to release one woman from under the machine. The car itself was badly damaged, having gone over an embankment at the side of the road.

CARBON DEPOSITS.

How to Remove Them and How to Avoid Getting Them.

"Carbon is one of the worst ailments of the engine and the most insidious," says William H. Stewart, Jr., president of the Stewart Automobile School. "Its presence is not suspected and the evils which follow are attributed to many other than the real causes. The motor seems to be sluggish, does not respond readily to the throttle, particularly on a hill, and the driver blames the gasoline, the carburetor, the cooling system—even the manufacturer. He gets out the starting handle and cranks the motor over to try the compression. He finds it weak and blames the manufacturer for making an engine which cannot hold compression a reasonable length of time.

"Before long the engine begins to miss explosions and he blames the coil or the spark plugs. He opens the switch after a long run and the engine refuses to stop. Then he remembers that he heard a distinct knock which he thought might be a loose bearing, but now he knows there is something wrong inside or the engine wouldn't overheat so badly after the careful handling he had given it. So he condemns the car and all its kind and asks his friends what the trouble is that so many ills can occur to one engine at one time.

"Carbon is the answer. It gets under the exhaust valves and gums up the piston rings so that the motor loses compression. It short circuits the spark

Digitized by Google

plugs and the engine misses explosions. It accumulates in masses in the head of the cylinder, gets red hot and fires the mixture before the proper time. This causes knocking, which is especially pronounced on a hill. When the switch is opened the motor keeps on running, as it was not using the electric spark at all.

"There are many causes of carbon and one must be on his guard against all of them. The usual trouble is too much oil, but the wrong grade of oil will give carbon as will a poor grade. Too rich a mixture from the carburetor is another cause. If the piston rings are badly worn oil will be drawn up into the combustion chamber on the suction stroke—more carbon.

"The remedy is to avoid the causes given above. Use oil made by the manufacturer of established reputation and use the oil he recommends for your car. See that oil level is correct and that mixture from carburetor is right. If red or yellow flame is shown at compression cocks the mixture is too rich. In spite of the best care, however, carbon will persist in forming. To help keep this down inject a small quantity of kerosene in each cylinder once a week. Have motor hot when it is poured in so that the kerosene will vaporize. Close compression cocks and crank engine over a few times, either by hand or self-starter. This compresses the vapor and forces it into the carbon. The effect of the kerosene vapor acting all night is to soften the carbon so that some of it will be ejected when the motor is again started.

"If such precautions have not been taken and cylinders are found to be carbonized, the deposits may be too thick to be affected by kerosene alone. The old method was to use scrapers which were inserted through the valve openings. The carbon was scraped off, but fell in masses on the head of the piston. Unless blown out it was carried into the muffler. If not thoroughly removed ridges of carbon were left which became red hot and caused preignition just the same. The best method, aside from removing cylinder head and positive scraping, is to have the cylinders burned out with oxygen. This can only be done when special apparatus is available. The engine is started and the gasoline supply is shut off. The engine stops, having used up all the explosive mixture in the combustion space. This is to avoid an explosion when the oxygen is first introduced into the cylinder. The plugs are then removed, a burning match dropped into the cylinder and the stream of oxygen turned on. This spreads to all parts of the combustion space, burning the carbon. As long as sparks are coming out the workman knows that there is still some unconsumed carbon. This process is quick and quite efficient, dismantling of motor being unnecessary."

Care in Washing a Car.

"Care in washing the motor car cannot be emphasized too much, for a presentable appearance after a year of service rests wholly with the attention that is given the body finish", says C. L. Hedges, manager of technical service for the Haynes Automobile Company, Kokomo, Ind., in a recent bulletin. Mr. Hedges' advice is applicable to any car, and for that reason worthy of the attention of every automobile owner. He writes in part as follows:

"The high gloss on a new car, in many instances, is lost in a short time because it is irreparably marred in the first washings. The varnish on a new car requires a month as a minimum time in which to properly set. In warm weather it is often advisable, with a newly purchased automobile, to shower the body, hood and fenders with clear cool water. This will aid in hardening the varnish coating and so reduce the danger from scratching and abrasion. The life of the finish on any car does not depend on the polishing action that is given in washing, but on quite the opposite. The body should not be rubbed any more than is absolutely necessary. In case the car is muddy, it is always well to remove the foreign substance as soon as possible to avoid spotting. This should be done with clear running water, first thoroughly soaking the mud, and then washing it off. On account of its scouring effect, water under pressure should never be used for this purpose.

"Perhaps the greatest enemy a high body finish has is a sponge in which sand or grit has collected. Even in the case of dust, it is better to remove this with slow running water. Dusters, which are employed by many owners, seriously affect the paint by turning the dust into an abrasive. When the body surfaces have been well cleaned off by running water, they should be gone over with a new sponge, care being taken that the sponge is always moved in a straight line. Following this treatment, the finish is to be thoroughly rinsed and then dried with a chamois skin, which should be thoroughly washed and wrung out during the drying process. This action, as well as the sponging, should be carried out with a straight-line movement. In most cases, the running gear and lower parts of the fenders should be washed first, as they are the dirtiest parts of the car. If grease and oil are present, the under surfaces should be soaked with a solution made by dissolving soap in warm water. The suds from this solution react on the finish and should be washed off immediately. Treatment of this kind, however, should never be employed on the body proper. The hood of a motor car should never be washed while it is warm since the rapid drying of the water deadens the finish."

Care of a Motor Car Top.

When a motor car top is folded for spring and autumn driving, the material is sometimes pinched by the bows or top fasteners and the fabric stretched out of shape. This can be avoided by care in lowering the top. An occasional brushing, inside and out, will keep the top in good condition and prolong its life.

The top may be washed with soap and water to remove the accumulation of dust and grease spots. Gasoline, however, should never be used to clean the rubberized cloth. It dissolves the waterproofing preparation.

Must Stay by Car on Ferries.

Motorists who drive onto ferryboats about New York City are notified by the deckhands to see to it that the driver remains at the wheel. This is because of a new law in New York State requiring such attendance when a motor vehicle is being carried on a ferryboat to or from a city of 500,000 or more population. Violation of the law is a misdemeanor. It became effective June 1.

Missing Numbers—Our Readers are requested to remember that it always gives us pleasure to re-send numbers which have gone astray in the mails.

The Automobile Dealer and Repairer in Australia and New Zealand.

Mr. R. Hill, Matlock House, Devonport, Auckland, New Zealand, is our accredited representative in Australia and New Zealand for obtaining new subscriptions.

A WRONG TENDENCY.

The increasing tendency of manufacturers to establish grocery and other supply stores for the exclusive use of their employes speaks well for their hearts but not so well for their heads. The idea is to carry a line of goods which are sold at cost, and of course a manager and a force of clerks are necessary to take charge of such establishments.

There is no reason whatever why workmen should not earn enough to be able to buy their groceries at the regular stores, and the idea of private retail stores is uneconomic and blighting to the retail trade to whatever extent it is practiced. The self-supporting grocer deserves just as much consideration as the employe or any one else. Suppose, for instance, that all big firms were to install retail stores for their employes, and that small employing firms were obliged to follow suit so as not to be handicapped in the remuneration of their help? Suppose the plan were widened until all employes were to buy not only food but all other things in this way? Of course, if the plan is a good one it will thus develop. But what of the general retail trade under such circumstances?

And if the retail trade is to thus take the new channel, why should not some good-hearted firms take the agency for automobiles and accessories or other manufactured goods in order to supply their help with them at less than the ordinary retail prices? Why not employ doctors and lawyers thus? Why not cut out altogether the retail trade from those who have learned it and who are getting their living by it, and at that under the sharpest kind of competition? Why not, in fact, turn the entire business world into a general eleemosynary system? Would the general welfare be thus promoted?

Something like this provision for inadequate wages has been practiced in Germany and in England for years, with not the slightest diminution of poverty, but with a narrowing rather than a widening of moderate welfare.

This is the first years of the 20th century. Anything in the nature of charity or benevolence, except in the case of "the lame, the blind, the halt and the sick"—those whom Christ said we should have with us always—is disgraceful. Give the people a chance to earn a living and provide against the needs of old age, and want will be unnecessary. Nothing would be a greater spur to industry than this, and those who are not impelled by this advantage to be industrious and thrifty deserve nothing better than the gutter.

THE GLITTER OF SUCCESS.

The public often charges great industries with making too much profit, and not because they know so much concerning these industries but because they know so very little. The critics are usually those who are half informed concerning the thing they criticise, rather than those who are fully informed. It is the old aphorism of "Fools rush in where angels fear to tread." This is the case with small business as well as large.

Take the automobile business, for illustration. There are more newly made graves in that cemetery of the departed than in any other industry of which there is any record, unless, indeed, it be the publishing business. According to one of the automobile directories, 718 companies failed or went out of business since 1912, and of this number 133 car manufacturers failed during the past two years. But in addition to this, other statistics show that more than one-half of our automobile manufacturers are breaking even only, and very few are making more than 10 per cent. annual profit on their investment. Of course, "all things are possible," but any one who imagines he can be successful in manufacturing a car of conventional construction today in competition with those already on the market lacks both business judgment and experience.

Just at the present time the cry of "robber barons" seems like a fetish running wild all over the country. No doubt there is a basis of fact for this complaint. When the demand for anything exceeds the supply high prices and unduly large profits must be expected unless the natural impulse of human nature is curbed in some way. But there are two sides to this question of curbing, and nothing should be done about it without full consideration of the fact that high prices invariably reduce the consumption of such articles, and often times to such an extent that the price raiser is sufficiently punished without adventitious interference. Take the case of potatoes, for illustration. This morning we note reports of prices being not more than one-third what they were two months ago. Now this falling in price is not due so much to increased production as to decreased consumption. Many families have stopped eating them altogether since the price began to soar upward. Demand and supply

Digitized by Google

have a far greater effect upon prices than cost of production, unless, indeed, the price of things is to be generally controlled by the government, which, except in case of absolute monopolies, heaven forfend us!

The talk of wonderful profits of the automobile business has led many an individual to part with his hard-earned dollars, never to see them again. The same conditions exist in the retail and "middleman" trade. There one would think from reports that profits might be picked up as easily as if they were berries. But there is absolutely nothing to prevent any one from embarking in such business. The required capital is not great, and nothing else is needed save industry and ordinary judgment. But the blasted hopes of the thousands who are constantly failing in each channel of enterprise are both instructive and melancholy.

Great successes glitter and flash out brilliantly, while failures slink away unseen and in silence. But the glitter of success is too often like the ignis fatuus, dragging on its victim to his destruction.

THE WHILOM JITNEY.

The jitney automobile service went up like a rocket a few years ago, but it bids fair to come down like a stick. Not that it could not easily be made to pay if the cities where it exists would confer upon the service the same favors it gives to the electric street car service—the right to use railway tracks and the right of way upon such tracks. Such tracks do away with the necessity of pneumatic tires and their comparative heavy expense, and a smooth track with hard tires will permit about twice the load for a given amount of power as when applied to ordinary traction.

But the jitney is otherwise handicapped just now by the high cost of gasoline fuel. In Louisville, Ky., the jitney service has recently ceased to operate. The thirty-four members of the Louisville Jitney Bus Co. have agreed to acquiesce in the will of the majority that business be suspended in July. The high cost of gasoline, which has increased from 9 to 24 cents a gallon since the buses started about two years ago, and of tires and accessories are blamed.

But in interurban districts the case is different. There, both passenger and express traffic will continue to increase and thrive.

FINDING MEN.

Men who are thoroughly competent to undertake the responsibilities of present day affairs and grow into the affairs of large concerns still are as hard as ever to find. Said one who has had long experience in the creating and filling—and keeping filled—of important organizations, "I have read five hundred letters of application for this one job and found only one applicant worth paying freight on for inspection. He didn't pass."—Exchange.

Nonsense! The failure to find suitable men is usually due more to the incompetence of the seeker of them than to the incompetency of the sought.

Lincoln was inefficient when he kept a grocery store. Grant was inefficient when he hauled cordwood. Graham Bell was inefficient when he was a deaf mute teacher. But neither failed when the responsibility came. Most of the successful men at the head of great business find no more difficulty than would be expected in finding competent men.

Any one who imagines that out of 500 applications for a job more than a very small per cent. will be thoroughly competent, is wofully lacking in common sense. It is the incompetent that are out of a job usually, and who are looking for work rather than the competent. And yet, on the other hand, the writer of this has in the past received applications for employment from men with threadbare collars and pantaloons frayed at the bottoms who were far more competent than himself, and yet he was obliged to "turn them down."

There are scores and perhaps hundreds of men employed in great industries who have the ability to manage them and possibly better than some of the men who are already at their heads. Henry Ford would have been called incompetent as long as he was a poorly paid machinist.

The men fitted for opportunities are as one hundred to one compared to the opportunities awaiting the man. We can never tell what a man is until an emergency calls out his reserve, and he cannot call out an ounce more than he has stored up. Moreover, he is the wisest and best man who puts the highest, not the lowest, esteem upon others.

NEW FLAG LAW.

Now in Force in Some States and Soon May Be in Others.

The law passed by the Texas Legislature to prevent and punish the desecration, mutilation or improper use of the flag of the United States or the Texas flag, became effective recently. The act prohibits the use of the United States flag for advertising purposes, and makes the improper use or desecration of the flag a misdemeanor, punishable by a fine not to exceed $100, or by imprisonment for not more than thirty days, or both.

Similar laws are already in effect in several States, this law having been copied from the Iowa and Nebraska statutes. Its provisions and penalties, specified in Section 1 of the act, are as follows:

"Sec. 1. Any person who, in any manner, for exhibition or display, shall after this act takes effect, place or cause to be placed, any word, figure, picture, design, drawing or any advertisement of any nature upon any flag, standard, color or ensign of the United States, or State flag of the State, or ensign, shall expose or cause to be exposed to public view any such flag, standard, color or ensign, upon which, after this act takes effect, shall have been printed, painted or otherwise placed, or to which shall be attached, appended, affixed, or annexed, any word, figure, mark, picture or drawing, or any advertisement of any nature, or who shall, after the first day of September, 1917, expose to public view, manufacture, sell, expose, give away, or have in possession for sale, or to give away, or for use for any purpose, any article, or substance, being an article of merchandise, or a receptacle of merchandise or article or thing for carrying or transporting merchandise, upon which, after this act takes effect, shall have been printed, painted, attached, or otherwise placed, a representation of any such flag standard, color or ensign, to advertise, call attention to, decorate, mark or distinguish the article or substance, on which so placed, or who shall publicly

Digitized by Google

mutilate, deface, defile or defy, trample upon or cast contempt, either by words or act, upon any such flag, standard, color or ensign, shall be deemed guilty of a misdemeanor, and shall be punished by a fine not to exceed $100 or by imprisonment for not more than thirty days, or both, in the discretion of the court, and also forfeit a penalty of $50 for each such offense, to be recovered with costs in a civil action or suit, in any court having jurisdiction, and such action, or suit, may be brought by and in the name of any citizen of this State, and such penalty, when collected, less the reasonable cost and expense of action or suit or recovery, to be certified by the County Attorney of the county in which the offense is committed, shall be paid into the Treasury of this State; and two or more penalties may be sued for and recovered in the same action or suit.

"The words flag, standard, color or ensign, as used in this subdivision or section, shall include any flag, standard, color or ensign, or any picture or representation, of either thereof, made of any substance, or represented on any substance, and of any size, evidently purporting to be, either of said flag, standard, color or ensign of the United States of America or a representation of either thereto, upon which shall be shown the colors, the Stars and Stripes, in any number thereof, or by which the persons seeing the same, without deliberation may believe the same to represent the flag, colors, standard or ensign of the United States of America.

"The possession, after this act takes effect, by any person, other than a public officer, as such, of any such flag, standard, color or ensign, on which shall be anything made unlawful at any time by this section, or of any article or substance or thing on which shall be anything made unlawful at any time by this section, shall be presumptive evidence that the same is in violation of this section, and was made, done or created after this act takes effect, and that such flag, standard, color, ensign or article, substance or thing, did not exist when this act takes effect."

THIS HAS THE PUNCH.

The War Situation and the Pressing Need of an Able Fool Killer.

From Homer McKee, Advertising Manager of the Premier Motor Corporation.—A fool can stand on the beach and let a little spray hit him in the face—and right away he wants to write a book on navigation. America's first battle in this war will be with the fools right here at home. A tongue without a brain behind it is as dangerous as a gun in the hands of a drunken Indian. This war is so big and so complex that a fool oughtn't to be allowed to monkey with it.

We keep cranks away from our powder factories and, by the same token, why shouldn't we keep fools away from our presses? Better still, why shouldn't we muzzle them and interne them till after the war? Here's what the fools are doing to us:

President Wilson, in his wisdom, exhorts the people to conserve their food stuffs. And he appoints this man Hoover, who, by the way, is the most expert food conservation specialist in the world, to help the people raise their truck and to make their truck go farther—all of which is wonderful generalship.

But the fools, who can no more fathom a deep mentality like that of President Wilson than a canary can whistle the Anvil Chorus, miss the whole idea and just manage to catch on to the tail end of the word "economy." So right away they want to go on a nation-wide hunger strike, start a bread line, and raise Cain in general.

Secretary McAdoo asks the people to buy some perfectly good, 3½ per cent. government bonds, non-taxable, the best investment that any sane man could make—because it is the safest. Right away, the fools shout, "Uncle Sam wants you to GIVE him your money." Fortunately, wise men are in a vast majority in this country, and the Liberty Bond issue went over with a bang. It was the wise men, though, not the fools that did it.

Some other fool shouted: "Let's all wear cotton!"—thoroughly ignorant of the fact that we need all the cotton we can get to make high explosives out of, for ourselves and our allies. If the so-called "Wear Cotton" propaganda had gone over, we would have had to fight this war out with fire crackers, or soda crackers, or pea shooters. That was a fine idea—wasn't it?

All of which goes to prove that we had better let the experts in this country—heaven knows we have enough of them—carry out the President's ideas. And the rest of us can find plenty to do keeping the fools from throwing wrenches in the gearset.

Right now the fools are busier than ever. Some of them are holding peace demonstrations down in Boston; and the rest of them are sitting up nights trying to work out new stunts for putting business on the "Fritz."

President Wilson, after conferring with delegates from the nations that have been in this war from the beginning, tells us that the all important thing for us to do is to KEEP OUR INDUSTRIES GOING.

In spite of this counsel, the fools are shouting at the tops of their voices: "Don't buy any automobiles!" "Don't buy any new clothes!" "Don't spend any money with the laundries—turn your collars wrong side out and wear them two days!" "Keep your wife away from the department stores!" "Don't let your children go to the movies!" "Don't do anything that will keep our factories and our stores and our places of amusement running!" "Close up everything and—pay the expenses of this war out of the excess profits of bankruptcy!"

The fools of this country might as well be made to understand right now and right here that we are not going to play into the Kaiser's hand by listening to their monkey chatter. We know just how serious this war is. But we know, on the other hand, that our fools are even more serious. We also know that no one ever won a war in sackcloth and ashes.

We must have business in this country. We must keep our heads up. We must preserve our prosperity, because America's wealth is her biggest gun. Shall we let the fools take the wheel at this dangerous turn in the road? Please, you 99 7/10 millions, answer in chorus—

"We will NOT!"

An Aluminum Racer.

The Frontenac car, with which Louis Chevrolet finished first in the 250-mile Speedway race at Cincinnati, doing 102.18 miles an hour average, is an example of the extensive use of aluminum. The

Digitized by Google

motor is almost wholly aluminum alloy, which weighs approximately one-third as much as cast iron. This includes cylinder block, clutch, housing, engine base, etc.

The whole power plant, including engine, flywheel, clutch, exhaust and starting crank, weighs only 490 pounds, and the entire car tips the beam at a trifle less than 1,600 pounds, or about 300 pounds less than the weight of any other car in the race. The Frontenac was built by Chevrolet on the idea that most racing cars were much heavier than they needed to be.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

2172 Will Not Throttle Down.

From John J. Berberick, Nebraska.—I have an Oakland 30-1910 car. It has a Remy magneto and coil and it has good compression. I put on a model D Schebler carburetor but can't throttle it down. The engine must run like sixty or as soon as I shut off the gas a little it stops. I have the spark retarded as far as I can. It seems to run pretty good at about 25 miles an hour, but when I shut off the gas it stops. I thought it was timed too fast. I think if I can retard the spark a little it would run slower. When I run the car 25 to 30 miles I do not have to advance the spark at all. I have tried it. I advanced it clear up and the car would stop. Now what can I do to slow down the engine when she runs idly? Is there no way I can make the drive pinion and bevel ring mesh a little deeper on this car? There is no way to adjust it. Could I put the washer on one side of the differential to make it mesh deeper?

Reply.—It is doubtful if an early spark causes your trouble, but it will be well to check up and see that it retards about one-third as far past top center as it advances before top center. It is more likely that the carburetor is not adjusted right for low engine speed. Other possible causes are,—an air leak through worn inlet valve stems; defective gaskets between the manifold and cylinders or where the carburetor joins the manifold; the magnets may be weak so that a good spark is not obtained at low speeds. To check this latter up, try decreasing the gap between the spark plug points. The bevel gears may be made to mesh deeper by placing a washer on one side of the differential, as you suggest. No doubt you will find a washer on the opposite side that may be removed or made thinner.

2173 Bothers About Starting.

From C. R. Dubia, Connecticut.—I have a 1913 Buick touring car. It has not a self-starter and bothers me about starting when I first crank it for a journey. After it gets warmed up and I stop it and start it again in a little while it starts easy. The car runs good after it gets started. Seems to me that the gasoline does not vaporize in the manifold. What do you think causes this trouble, and how can I remedy it?

Reply.—Starting is sometimes made difficult by late ignition. Check up the spark and set the lever so that it occurs on top center or very slightly after. This trouble has often been traced to too wide or too narrow spark plug gaps. A wide gap is desirable for easy starting, but sometimes the spark generated is weak, making a narrow gap necessary. We would suggest that you make sure that you are obtaining a good spark and then experiment with different length spark plug gaps. Worn inlet valve stem guides admit air and make starting difficult. A little experimenting will bring out the fact that the engine starts best with the throttle lever set at some certain position. A closed choke valve in the air intake of the carburetor also helps to make starting easy. If attention to all of these points fails to accomplish the desired result, we would suggest installing a gasoline primer on the inlet manifold or combination spark plugs and petcocks, so that a small quantity of gasoline may be introduced directly into the cylinders.

2174 Carburetor Trouble.

From Richard J. W. Krebs, Ohio.—I have a Ball & Ball duplex 2-stage carburetor on my King eight-cylinder car. The carburetor spits when it is running below 15 miles per hour. If I give it more air it does no good, nor does it if I cut it down and give it a real rich mixture. Can you tell me where my trouble is? My car has a single dry plate type of clutch which slips. I cannot adjust it, so that it does no good. Will you tell me how to fix it? Do you think it needs a new disc? If so, give me instructions how to put in a new disc. The car has only run 4,000 miles.

Reply.—Your trouble may be due to a small amount of water in the carburetor or to a partially clogged primary spray nozzle, or if the popping back occurs as the throttle is being opened, the plunger in the pick-up tube may stick. Remove the four plugs in the bottom of the carburetor so as to drain out any possible water or dirt, and inspect the primary spray nozzle. Also see that the pick-up plunger moves freely. If the trouble does not prove to be in the carburetor, examine the inlet valves for a possible leak and test for a weak valve spring or a sticky valve. Sometimes a valve will stick open at low speed and not at high, especially if the spring is weak. This clutch may be adjusted by removing the square cover on the rear of the fly wheel housing underneath. There are two cap screws set in curved slots in the clutch cover. These may be observed by having the engine turned over slowly by hand. To increase the tension, have the clutch pedal pressed down, back off on the cap screws slightly, move them to the right and then retighten. Sometimes oil works into the fly wheel case and gets into the clutch. In this case adjusting will do no good. It will be neces-

Digitized by Google

sary to remove the entire oil pan from the bottom of the motor and unscrew all of the cap screws on the clutch cover about 3/16 of an inch. Then squirt gasoline into the clutch housing to wash out the oil. Drain out all the oil in the fly wheel compartment of the oil pan and inspect the partition between it and the crank shaft compartment for leaks.

There are a number of automatic decarbonizers on the market, most of which do the work in good shape. About two tablespoonfuls of kerosene introduced into the cylinders twice a week when the engine is hot, will keep them fairly free from carbon. It is best to turn the engine over a few times with the ignition off and let it stay in over night.

2175 **His Oakland Six.**

From M. Irvine, Maine.—1.—I have an Oakland Six, Model 32-B, and it has three-quarter elliptic springs on the rear. Could I have cantilever springs installed in place of the above springs, and would it be advisable to do so? How much would it cost to have it done, and also where could I get the cantilever springs? If so, what size springs would I want to order? 2.—There is also a clicking noise I think in No. 1 cylinder, and the spark plug in this cylinder carbons up awful bad. Do you think there is a piston ring broken? Also when I run the car up to 20 or 25 miles an hour there is a chafing noise somewhere in the engine. It sounds like two pieces of sand-paper rubbing together. I have not run this car over 2,000 miles and the chafing sound grows louder all the time. If I throw out the clutch and let the engine run it has the same sound. Can I remove one of the pistons without taking off the top of the engine?

Reply.—1.—No doubt it is possible to make this change, but we do not believe the improvement would be great enough to warrant the expense. The Harvey Spring Co. of 849 17th St., Racine, Wis., or the New Era Spring & Specialty Co., 871 Woodward Ave., Detroit, Mich., could doubtless advise you as to the size of spring necessary and the probable cost. 2.—A broken piston ring would give this sound and might score the cylinders so that the oil would work by the piston. This might also account for the chafing noise, although from the description, this noise might be due to the passage of air through the carburetor or to a dry fan bearing. The piston may be removed through the crank case.

2176 **Certain Inquiries.**

From A. E. Sears, California.—1.—My small pinion is chipping the teeth on the fly wheel quite badly when using the self-starter. Is there any way to remedy this? 2.—Does running an engine for a time on pure kerosene have any effect on carbon? 3.—What is the cause of a valve click? 4.—I was told by a demonstrator that the Delco system of getting a spark from the generator was the same as a magneto, which I do not credit. 5.—Will some reader tell me how to shift gear from high to second, on Model 83 Overland? I have never been able to do this without a bad clash.

Reply.—1.—If this starter employs the Bendix automatic meshing device, it may be found that the spring attached to the pinion and motor shaft has a kink or bend in it, which sometimes happens when the engine kicks back. This does not allow that required action when the gears are meshing and the teeth of the hard pinion striking against the soft teeth of the wheel, chip them. This may also happen if the gears are out of alignment or if they mesh too deeply. In other cases where cast-iron fly wheel gears have been used, it has been found necessary to leave the meshing face of the fly wheel teeth blunt, and chamfer off the back part of the tooth of the driving pinion so that the meshing face of the tooth is a sharp point. This allows for greater strength to the soft cast-iron tooth, and prevents chipping. We presume that you do not refer to the Delco starter mentioned in question 4, as this type has either no gears or a series of gears. 2.—Running an engine on kerosene would, no doubt, increase the carbon deposit. A small amount of kerosene injected into the cylinder and allowed to stand for several hours, would loosen the carbon, which would be blown out through the exhaust port when the engine was started. 3.—A valve clicks when it strikes its seat. It may also click from too much play between the valve stem and the push rod. The push rod should be adjusted as close as possible without holding the valve from its seat when the engine is hot. Another so-called valve click is due to a worn push rod guide that permits a side movement in the push rod when the cam passes center. 4.—The Delco ignition system is very similar in principle to the magneto system which uses an external coil, the only difference being that the Delco generator gives a direct, practically constant voltage current so that the spark may be taken off at any position of the armature, while the magneto generates an alternating current with considerable variation of voltage so that the interrupter points must open when the armature is in certain positions in order to procure a good spark. The quality of the two sparks is very similar. The self-contained, true high tension magneto is different in many ways from the Delco system and generates a much heavier or thicker spark, which would not jump quite so great a gap. 5.—The gear may be shifted from high to second on any car in good condition, provided the car speed is reduced to eight miles an hour, the clutch fully released and the shift made quickly. The shift may be made at higher car speeds by releasing the clutch, shifting to neutral, engaging the clutch, accelerating slightly, disengaging the clutch and shifting to second. Will some reader tell how he does it with this car?

2177 **Carbon Removing.**

From Wilbur F. Hastings, Massachusetts.—Will the injection of a small quantity of water into the cylinders immediately after running have the effect of breaking up the carbon deposit so that it can afterwards be blown out by inserting the nozzle of the tire pump through a valve port? I have heard this was a good idea and effective as a carbon remover.

Reply.—We would not advise this method as effective. Water has little or no effect upon carbon deposit. Moreover, it might result in an injury to the piston if the water came in contact with it when the piston were hot and the water were cold. It would of course, generate some steam, but in our opinion it would have no effect whatever on the carbon. Preparations are made which have a loosening effect upon carbon so that it may be removed easily. One such

Digitized by Google

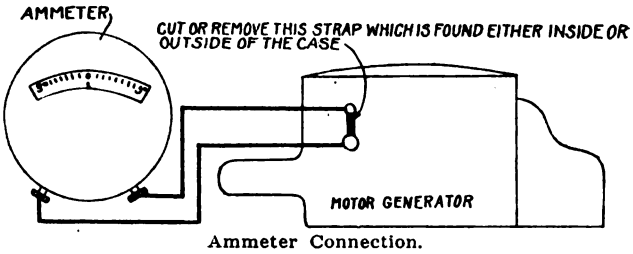
carbon remover is being advertised in this magazine and it is guaranteed to do what is claimed for it. It is called Johnson's Carbon Remover and is made in Racine, Wis. Why experiment with doubtful methods?

2178 **Starter Trouble.**

From William Cheesman, New Hampshire.—I have a 1914 Model B-25 Buick touring car equipped with Delco starting and lighting system. I have run it about 7,800 miles. My trouble is this: When I press the starting lever the gears of the starter wheel will not mesh with gears of fly wheel. To turn motor over I often have to open the hood and turn the starter wheel a little to have them mesh. I took it to a battery service station. They said the armature would have to be turned down and the mica cut so that the brush would hit the copper, and that was done but made no difference. Then the service man said the coil had gone bad, so put in a new coil with the same results. Then he said the cut-out relay in the generator was bad, so I had a new one put in and still the same trouble. When I first got the car its gears did not mesh. I would let up on the starting lever and the position of the little wheel would change, but now it won't stir unless I turn it by hand.

Reply.—If the battery does not become quickly discharged, the generator armature and cut-out relay must be all right. There is a small arm with a plunger backed up by a spring, which closes the points on the cut-out relay when the starting lever is pushed down. This arm is operated by the rod that slides the starting gears into mesh. It is quite likely that the spring has become weakened or the plunger stuck down so that the cut-out points are not pushed closed. This would prevent the armature from revolving slowly in order to make the gears mesh easily. As there was difficulty in meshing the gears even before the armature stopped operating, it is likely that the small gear meshing with the fly wheel meshes too deeply. This may readily be overcome by setting the generator a little higher. Trouble with meshing gears might also be caused by depressing the starting lever too quickly. The movement should be made slowly in order to give time for the armature to turn over before the gears are meshed.

2179 **Ignition or Carburetor Trouble.**



From Theodore Stremme, Colorado.—I have a 1915 4-cylinder Velie and do all my own repair work. I don't know much about cars, but I can do as well as the garage men in this town do, as they never have a good repair man. I also wish to ask you what you think the trouble is, whether the mixture is too rich or too lean. I have never changed my carburetor, which is a Stromberg G-1. The exhaust is awfully strong and makes your eyes just burn when I run the car into the garage, and pump up a tire with the engine pump. I don't quite understand it, as it didn't use to do that, and I haven't changed the carburetor at all. And when I first start the engine it snaps and seems to explode in the exhaust manifold. My engine heats up much quicker than it used to. I have cleaned the engine and radiator out in good shape but that doesn't seem to help the overheating any. If you can tell me what the trouble might be I will be very grateful to you.

Reply.—The trouble described might be due to faulty ignition, rather than faulty carburetion. A poor spark, due to dirty interrupter points or other causes, would give all the symptoms you describe. On the other hand, the quality of gasoline has probably changed enough in the past two years to make adjustment of the carburetor necessary. We would suggest that you check up the ignition, examine the carburetor float for a leak, and then adjust the carburetor for a leaner mixture. Also, examine the valve push rod adjustment to see that the clearance is not too great, and drive with the spark as far advanced as possible without causing the engine to knock.

2180 **Ammeter for the Dash.**

From Robert C. Ford, Michigan.—Will you please tell me how I could wire a dash ammeter to a 1914 Buick car?

Reply.—If it is a B-24, 25, 36 or 37 there is a metal strap connecting the two terminals on the motor generator. If the strap is found on the outside of the casing, it may easily be removed or cut.

Ammeter Connection.

Some of these machines have the strap on the inside, in which case it is necessary to disassemble the motor generator to remove it. After this has been done, connect ammeter as shown in the accompanying diagram. If the car is a Model 54 or 55, the red wire leading from the No. 4 terminal on the starting switch to the No. 2 terminal on the cut-out relay should be disconnected at the relay end. This end may then be connected to one terminal of the ammeter and another wire run from the other terminal of the ammeter to the terminal on the cut-out relay from which the red wire was disconnected. It is not possible to have the ammeter show the current drawn by the lamps in this case.

2181 **Starting Motors.**

From James Laurie, Pennsylvania.—Please tell me about how much power the ordinary small electric starting motor will develop. I know of one that seems to easily crank an engine that can not be turned over by hand, but I can't see where it get its power from.

Reply.—A small electric motor can develop much power for a short time providing it has a large and well charged battery to draw current from. Possibly some of these motors may give as much as a half horse power for a very short time. Such a motor is not made to give a large output for any length of time.

2182 **Clogged Radiator.**

From Dr. Z. W. Seibert, Ohio.—What makes my radiator get too hot on one side and the other side

Digitized by Google

stays cool in my Buick D-44? The pump seems to work all right. Taking off the filling cup while engine is running, the water seems to circulate all right. Have washed it out with soda solution. What is the remedy?

Reply.—Apparently, the radiator is clogged on the side that stays cool. We would suggest that you take the radiator off, turn it upside down with the filler-cap off, and feed water from a hose under pressure into the outlet pipe at the bottom of the radiator. This may force back any stoppage. If not, it will probably be necessary for a radiator repairman to take it apart.

2183 **Compression and Batteries.**

From K. E. Hillestad, Colorado.—1—If compression is weak and too much carbon forms in combustion chamber, continually fouling the spark plugs, is this not a sign of poorly fitting or worn piston rings? And if so, would not a good type of leak proof rings remedy the trouble? Would you recommend a full set of leak-proof rings or just one or two to each piston, and what type of ring do you recommend?

2—A storage battery fully charged should show a specific gravity test of 1.280. Mine are down to 1.200—one cell as low as 1.150—but seem to work all right and start the car properly. I asked my garage dealer about this, thinking they ought to be recharged up to the standard test, but he informed me that this was not necessary so long as they started the car properly regardless of what test they showed. Perhaps he was busy and did not want to bother with a small job like this when there was plenty of other work in sight. What is your idea in regard to this matter? Kindly explain fully.

Reply.—1—Poorly fitted piston rings will give the troubles described; however, with well-fitted rings the same results may be expected if the oil level is too high so that too much oil is fed to the cylinders. Sometimes leakproof rings installed in the top groove or the two top grooves often will help, but properly peened standard rings will do just as well provided the cylinder is not worn out of round or scored; in which case neither type of ring will do much good and it will be necessary to have the cylinders rebored or ground. 2—A cell is usually considered to be fully discharged when the specific gravity of the solution tests 1150. Although the battery in question will crank over the engine it should have immediate attention, as further discharge will sulphate the plates of the low cell to such a point that it will take extra coaxing to bring the battery back into shape. It is unfortunately the usual practice to discharge the battery until it will no longer do the work required of it and then give it some attention, but it is much less expensive and more satisfactory in every way to have the battery recharged just as soon as the specific gravity drops to 1150 in any cell. When recharging, care should be taken to have all three cells brought up to the same specific gravity, and if the cell which is now low does not hold its charge as well as the other two cells, it should be taken apart and examined for an internal short-circuit.

2184 **Leaks Grease.**

From F. C. Ostrander, New York.—The differential of my car leaks grease to the extent that it gets on the fiber, and I have difficulty in getting up the steep hills or starting in bad places. Being a rural letter carrier, I have to start from the ditch about ninety times per day. I have tightened the bolts in the differential until I have spoiled the threads, and have put in new bolts, yet it will leak grease.

Reply.—As you do not state the make of the car or just where the grease leaks through, it is impossible to give specific directions. This trouble may usually be overcome in any case by installing felt washers around the shafts or felt gaskets at any of the joints. Perhaps you use too light a grease or too much of it. The grease should be fluid but not thin and just enough to allow the gear to dip about two inches will be found sufficient if checked up often.

2185 **Radiator Boils.**

From L. A. Brown, Florida.—I have lots of trouble keeping water in my 1915 Baby Grand Chevrolet car. I can fill the radiator and before I have run any distance hardly it is boiling and I have to fill it about every ten miles. Please advise a remedy.

Reply.—In the first place run your car with the spark advanced as far as possible without causing the engine to knock. Retarding the spark causes overheating as does too much play between the rocker arms and valve stems. Fill the cooling system with a strong solution of washing soda in water and run for several hours. Then drain off the solution and flush out the system with fresh water by disconnecting hose connections and feeding water from a hose into the top of the radiator and the water pipe at the top of the cylinders. The fan belt of this car must be kept very tight to have the fan revolve at its full speed. A rich mixture would also cause the engine to overheat and it may be advisable to get a smaller spray nozzle for the carburetor, if the Zenith type is used.

2186 **Gear Changing.**

From a Subscriber, Pennsylvania.—Please state in your next issue if there is more than one way to make a silent gear change from high to second on cars requiring to drop to or below ten miles per hour.

Reply.—The best way to change the gear from high to second is to slow the car to a speed which permits a silent shift with the clutch fully released and a very quick movement of the gear shift lever. This speed will range from five to fifteen miles an hour in different cars. There are times, as in climbing hills, when it is desirable to change the gear when the car is traveling at a higher speed so as not to lose momentum. This may be done by setting the throttle slightly open so that if the clutch were released the engine would speed up slightly but not race excessively, and then shift with the clutch partly disengaged. To shift the gear from high to second at very high car speeds, release the clutch, move the lever from the high speed notch to neutral, engage the clutch, accelerate, disengage the clutch, and move the lever to the second speed notch. The two last methods require considerable

Digitized by Google

practice before the novice can successfully carry them out, therefore, we advise the first method.

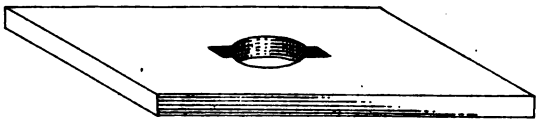
2187 **This Peculiar Motor Trouble.**

From J. H. Ewing, Tennessee.—The writer has a Dodge Bros. car which he has had for about two years. I took it to our garage man here and he has made a test of the compression and the spark plug cutout, and when he "shorts" any two of the plugs the other two carry the motor over and hit in proper time, but as soon as he releases them the motor goes to missing. When I am on a pull it takes hold and develops well and seems to have plenty of power. If you can enlighten me in regard to the above trouble I will greatly appreciate it.

Reply.—This seems to be a case of what is known as "the engine running away from the gas." With the engine throttled down, the compression is low and the gasoline and air are not well mixed. This makes ignition uncertain. Short-circuiting two sparks is equivalent to running the two live cylinders under load, and they will fire all right. But when all four cylinders are operating, the engine speed developed without load is sufficient to cause the missing described. Widening the spark plug gaps or slightly enriching the mixture or both will, no doubt, overcome the trouble.

2188 **Motor Not Pulling Good.**

From M. E. Richardson, Tennessee.—I let the oil run low in my Ford car. I ran it until I noticed that it was not pulling good, and when I examined it, there was only one pint of oil in it. I also found some small pieces of metal in draining out the oil. After draining out the oil I refilled it and cranked it up, and it seems to run as well as ever. But at times I can hear a knock, that is, when the engine is running slow, and not pulling. Please advise me in your next issue if it is all right to run it as it is or should I have it examined.



Reply.—It is quite likely that when you ran the engine without oil one of the crank pin bearings became burned or partly melted. If the pieces of metal found in the oil were any larger than dust, it is evident that the bearing is breaking up and may suddenly go to pieces at any time. The engine, by all means, should be taken apart and the bearings carefully examined.

That Back Lash.

From George A. Lippincott, New Jersey.—I have read No. 2169 in your June issue and have had the same trouble with my Chandler Chummy roadster, model 17. Have had it to all of the garages in this section of Long Branch and none of them could locate the trouble. So I took it upon myself to locate the trouble. My car would work all right in high speed, but when I slowed it down there would be a "back lash," so I came to the conclusion that it must be in the low speed adjustment of the carburetor as it worked all right in the high speed. I took my car on the road and kept adjusting the low speed and the first thing that I knew the back lash was gone. I was not satisfied with that, so I adjusted the low speed back again and the "back lash" appeared as before, so I was satisfied that the trouble was in the adjustment of the carburetor. I have adjusted several Chandler cars that have had the same trouble as mine, and they are all right now. If you think well of my suggestions you can try it and I would be pleased to hear of your results.

Right-Hand Screw Plate, Left-Hand Thread.

When left-hand screws are desired and only a right-hand screw plate is available, the left hand plate shaped as follows will, upon a pinch produce fairly satisfactory threads. A screw is first cut with the right-hand die, and a tap made from it by cutting away the threads on two opposite sides of the metal as shown in the accompanying illustration. The tap should be tempered and a hole of the

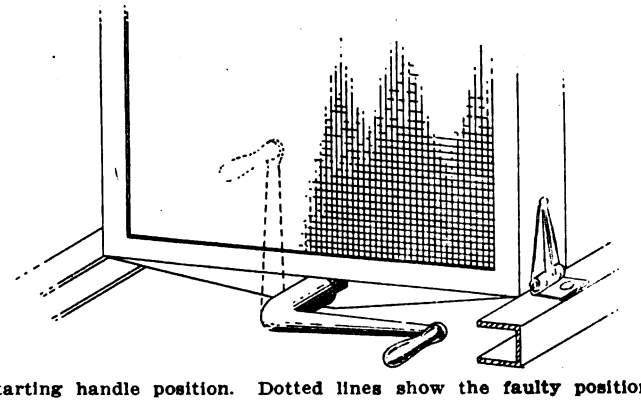
Left-hand Plate

same diameter as the body drilled in a piece of steel of the proper size. The tap is then placed in the hole and turned to the left while applying considerable pressure. The tap should be turned slowly and the pressure applied steadily in order to ensure a clean cut. If necessary the plate thus made can be shaped and slotted, after which it should be tempered. The screws cut by this plate will not be quite perfect, but will do in an emergency.

Oiling Automobile Springs.

From J. O. Hess, Missouri.—In a recent issue I find an article on oiling automobile springs. Now prying the leaves apart with a chisel, screwdriver or other such instrument to oil the spring seems like giving it a harsh and unmechanical treatment. There are devices on the market that obviate the necessity of such methods. But if one does not happen to own one of them, or is unable to pay the price asked for it, he might adopt my own method, which is as follows: I make a wooden pin ½ inch round, long enough to reach the side of the spring in a vertical position. I have some common yellow soap, worked and kneaded to about the consistency of stiff dough. I put the ½ inch round stick against the spring so that the lower end of the stick comes to the upper edge of the lowest plate in the spring. I now plaster around the sides of the stock and lower end with soap and then withdraw the stick, which leaves a pocket across the side of the spring. I fill this with lubricating oil; capillary attraction does the rest. The oil will penetrate through clear to the other side and clear down to the points of the leaves, oiling the spring completely. I do this of an evening, Next morning I take off the soap oil cups, wipe off all surplus oil and it is wonderful how much easier this spring will ride and keep the unsightly rust off. If I have occasion to take a spring out, I clean all the plates and go over them—first with a coat of paraffine and then dust on flake graphite.

Who Can Tell?



From B. H. H., Pennsylvania.—I have a Crow-Elkhart, model 30, year 1916. I have broken three axles, three pinion gears, one ring gear, one universal joint, all on account of the clutch. It is a dry disc, Raybestos lined. Now if you loosen this clutch it will not pull the car and when you tighten it you nearly always break something. I wrote to

Digitized by Google

the Crow-Elkhart people and they admitted that the car would do this, but said that they had a clutch attachment that they would send me that would remedy this. I tried this, but I find that it is no better. The repair man that does my work says the trouble is that they drive the car from the rear springs and that as the transmission is on the rear, when you start there is enough play in the springs so they force the drive shaft and all forward in to your clutch, causing it to grab. Now when you go to back up, this does not happen. Could you tell me how to remedy this, or maybe some other reader has solved the problem and will tell all your readers how.

The Starting Handle.

From Geo. Norton, Delaware.—The idea that the starting handle should be in a vertical position with the grip uppermost is not a good one. In the event of a collision, no matter whether this were more or less serious, the starting handle grip would probably receive a blow, and as a result, the lever would be

Starting handle position. Dotted lines show the faulty position.

driven back into the radiator and cause damage to it. In my opinion, therefore, the best position to fix the starting handle is so that the grip is not in front of the radiator, but rather in front of the chassis cross-member, so that the latter would take the force of the blow if the handle itself should be knocked back. The alternative positions are indicated in the accompanying sketch.

"Pleasure" Not the Right Word.

From Advertising Manager Chevrolet Motors Company.—Let's start a movement to eradicate the word "pleasure" from the automobile vocabulary. It hasn't any place in it. It is this same word that has caused so much glee in Washington lately. Each Congressman I have heard has put special emphasis on the word "pleasure." It is meaningless. It is not correct. Let us cut it out of every catalogue, of every advertisement, from every printed statement.

Let us all start using the word "passenger." That is the word to use, and it is the proper one. The automobile used on the farm isn't used for pleasure purposes. The automobile used to save patients' lives isn't used for pleasure purposes. The passenger car used on any business errand isn't used for pleaure purposes. And so on indefinitely. Let us wipe out the word "pleasure" as applied to an automobile.

A GALLON OF GASOLINE.

And How to Get as Much Service Out of It As Possible.

With the price of gasoline going up every change of the moon, says H. C. Brokaw, principal of the Y. M. C. A. automobile school, New York City, with the increased cost of tires not only possible, but probable, and the tariff for everything else needed for automobile upkeep on the ascent, it is time for the owner to consider his expense and renewal costs. And when it is considered that repairs and labor have pirouetted skyward along with other things, it behooves the owner to consider ways of decreasing running expenses, and to learn how to get as much out of a gallon of gas as possible, not to say every mile out of his tires they can be coaxed to give.

There are many little expenses about running a car which total a considerable sum. The Scotchman puts it: Mony a mickle makes a muckle." A nickel, a dime, a quarter, a dollar, do not seem much at the time, but they pile up the cost per mile frightfully. Not every one can be like a friend, who, when cautioned about the way his chauffeur was running up the cost of his several cars, replied:

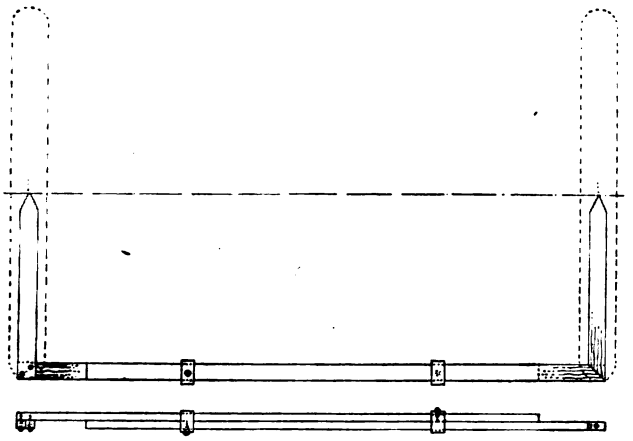
"I don't want to know what my cars cost. If I did, my business instinct would doubtless make me dispose of them all, and I do not want to do this. The cars are a luxury and I don't want to know what they cost."

A car which lasts, with ordinary care, one or two years, if given intelligent care by the owner might be made to last three to five years. This means taking extraordinary care and a thorough knowledge of the working parts and how to keep them in condition, and it means doing faithfully and persistently the things necessary to keep everything in order.

When it is considered that, with real war at hand, it may not be possible to get a new car as often as it has been in the past, it might be as well to take care of the cars we have, rather than let them go to rack and ruin for lack of care. We are howling about food waste by the American people and it is about time we hear something about waste of automobiles. A good many automobiles are wasted more than they are used. In some cases this is due to carelessness and in others by lack of knowledge of what to do and how to do it.

Take tires, for instance. The cost due to neglect is often greater than the cost of actual wear. Some of the things which cause excessive wear and deterioration of tires are: driving into holes in the street, or in deep cuts; turning corners at too high speed; stopping the car so quickly with the brake that the wheels slide on the pavement; and a harsh clutch which jerks the car suddenly from a standstill, causing needless wear. Then there are such things as letting the front wheels get out of alignment, so that they do not run parallel, or nearly so, the action being that the tire is slid instead of being rolled over the road. There should be a slight toe in, for mechanical reasons, but if this is allowed to go beyond the proper limit it costs money.

Adjusters tell us that a very large percentage of tire failures is caused by under-inflation, which allows the tires to flatten and breaks the side walls. Every tire should be tested with a gauge and not



Digitized by Google

with the eye or hand, and kept to the pressure named by the tire maker.

To get the greatest life out of a tire it should be watched continually for small cuts through the rubber to the fabric. Most tires will be found after a short service to have from two to a dozen such cuts. These will allow sand to work in and loosen the rubber and then moisture gets in and rots the fabric. There are preparations with which these cuts may be healed in a few minutes; serious cuts, especially where the rubber is loosened from the fabric, should be taken at once to the vulcanizer.

While oil and grease of good quality cost money, their proper use will save many times their price in replacement of parts. On the other hand, a waste of lubricant makes unnecessary expense. Especially with a new car, oil and grease should be watched carefully until the bearings have had time to work in. That is the time when expense for replacement of bearings is most likely.

It is not generally realized that a large number

Method of checking up wheel alignment.

of things enter into the economical use of gasoline. To get the most out of a gallon of gasoline all moving parts must work properly. This means proper lubrication. The brakes should not drag; each cylinder of the engine should fire properly; the clutch should not slip; and the carburetor should be in proper adjustment. It is not well to adjust the carburetor unless sure it is at fault. Excessive carbon in the cylinder causes a decided loss of power, due to back pressure on the piston, and the partial clogging of the muffler indirectly consumes extra gasoline. The importance of keeping the muffler free is not usually understood.

Some time ago I was riding in a car that could hardly make headway against a strong wind blowing. This meant frequent use of the second speed gear, which in itself causes an undue use of gasoline. I found on experimenting that the muffler cutout pedal could be used in place of the accelerator pedal; that is, when the muffler cutout was open the engine had considerable more power and immediately speeded up. The fact is that we kept that cutout open most of the way home and had no more trouble in bucking the headwind. It led to the discovery that the muffler was almost totally clogged with carbon.

To insure each cylinder getting its proper power without waste, the engine should be driven with the spark lever advanced as far as possible without causing back pressure. The spark plug gaps should be adjusted properly to insure a thorough ignition of the charge; the spark plugs should be kept clean to prevent the loss of a charge of gas through non-ignition, likewise the interrupter points and the distributor should be kept clean and properly adjusted.

To use all the gas that is taken into the cylinder there should be no loss of compression through leaky valves, or weak valve springs, or poor gaskets on spark plugs or valve caps; and it is equally important that pet cocks, cylinder head, where there is one, and piston rings are tight, so that gas will not waste.

It is not safe to leave these things to the chauffeur and the garage man. The owner should learn how himself and see that everything about his car is adjusted right and he ought to know how to keep them in order. If he gets this knowledge inside his thinking machine he will find that his propelling machine will work better, and that he will not only have more use and pleasure out of it, but he will save a very appreciable part of the cost of upkeep.

THE LEGAL ASPECT.

It Will Pay Every One Interested in the Automobile to Read This.

Liability for Injury to Guest in Car.—The Louisiana Supreme Court holds that the driver of an automobile is not liable in damages for personal injuries inflicted upon his guest in the car as a result of an accident, where the facts are as follows: The driver had inquired about the condition of the thoroughfare before entering it and was informed that it was all right; the car, while traveling at a moderate speed on a prominent street in a city, ran into an open canal extending across the thoroughfare, without any guard rail, barrier, red light, or other warning of danger; the glare of an electric light between the driver and the canal prevented his seeing the danger until it was too late to stop his car while going at an ordinary speed; the driver had never traveled over that route before and had no knowledge of the dangerous situation; the guest in the car had traveled over that route several times before and was acquainted with the situation, but did not warn the driver or complain of the speed.—Jacobs v. Jacobs, 75 So. 992.

Liability for Acts of Adult Daughter Driving Car.—A member of a real estate firm which owned a motorcar allowed his family to use the car when it was not needed for his business. His adult daughter, without his express consent, took the car on Sunday for a pleasure trip, on which she collided with another car, whose owner sued her father. The Mississippi Supreme Court holds, Woods v. Clements, 74 So. 422, that the defendant's daughter was not his servant in the operation of the car, and he was not liable for her negligence under the doctrine of responsibility of a principal for the acts of his servant or agent.

Construction of Contract to Sell Automobiles.—A dealer's contract with an automobile manufacturer to sell only a restricted territory was secured by deposit with the manufacturer and provided in terms that it should apply to machines in the dealer's possession upon its termination. The Kansas City Court of Appeals holds, Coleman v. Ford Motor Co., 193 S. W. 866 that the deposit may be forfeited where

Digitized by Google

the dealer sells outside his territory after the termination of the contract by the manufacturer. A contract may provide for the rights and liabilities of the parties upon its termination.

Automobile Insurance.—The New York Appellate Division holds, in an action on an automobile insurance policy, Callahan v. London & Lancashire Fire Ins. Co., 163 N. Y. Supp. 322, that the fact that plaintiff's automobile was stolen from a garage owned by a corporation of which he was president, the caretaker of the garage being implicated in the theft and subsequent wrecking of the car, did not establish its damage by a person in insured's employment or service within the non-liability clause of an automobile theft insurance policy. Under an automobile policy insuring against theft, etc., the insurer is liable for the total value of a car wrecked after being stolen.

Measure of Damages for Breach of Warranty.—In a suit for the purchase price of an automobile used by the plaintiff for several months before it was returned to the defendant, the measure of damages, if any, for breach of warranty was held to be the difference between the purchase price of the car and its market value on the date of the purchase.—Cook v. Robinson (Ga.) 91 S. E. 427.

Care at Railroad Crossings.—The Kansas Supreme Court holds that the rule that it is negligence as a matter of law for the driver of an automobile to attempt to cross a railroad track without stopping, where without doing so he cannot assure himself that no train is approaching, does not apply where, as the automobile approaches the crossing, the train is standing still, the rear end being near the highway, and a collision results from a sudden starting of the engine. In such a case whatever risk he runs is that the engine may suddenly start up, and stopping his car and going upon the track to look would not give him any additional information as to the likelihood of that taking place. It holds the question whether ordinary prudence forbids his attempting to cross the tracks without further investigation is a fair one for the jury.—De Hardt v. Atchison, T. & S. F. R. Co., 163 Pac. 650.

Knowledge of Right of Way Ordinance.—The Colorado Supreme Court holds that where an ordinance gave one driving an automobile the right of way across an intersecting street and required him to look to the right, one approaching on the intersecting street on a motorcycle with his view unobstructed was bound to know that a vehicle on the other street had the right of way, and his failure to make an effort to look for an approaching vehicle resulting in a collision is contributory negligence so proximately connected with the injury complained of that but for such negligence the injury could not have occurred, and which will bar recovery.—Livingston v. Barney, 163 Pac. 863.

Construction of Contract to Deliver Automobiles.—Under a contract by a manufacturer of automobiles to deliver cars on orders from a dealer f. o. b. Detroit, to be paid for on or before delivery, the Federal District Court for the eastern district of Pennsylvania holds that the dealer could not recover damages for failure to deliver, without proof that it gave shipping directions, and of its readiness to make payment, or of waiver of such condition.—Weinstein v. Studebaker Corp., 238 Fed. 963.

Contracts Between Manufacturer and Dealer—Lack of Mutuality.—A manufacturer of motor cars by written contract granted the right to a dealer to sell its cars within a certain territory for a certain period, and the dealer agreed to purchase a stated number of cars each month during the term of the contract, but the contract did not obligate the manufacturer to furnish the cars, and further provided that it might be canceled by either party at any time on 15 days' notice. The Federal District Court for the northern district of Georgia holds the contract is void for lack of mutuality and unenforceable by the dealer or his representative.—Ellis v. Dodge, 237 Fed. 860.

Breach of Conditional Sale of Automobile—Measure of Damages.—K. sold an automobile to E., taking in payment part cash and notes for the balance and retaining title to the automobile until the purchase price should be paid in full. The notes provided that in default of payment or in case of alienation of the property by the maker of the notes the payee should be authorized to take possession of the property. In an action of replevin for the automobile by K., the Florida Supreme Court holds, Evans v. Kloepfel, 73 So. 180, that upon default by the purchaser to pay one of the notes at maturity K. could maintain the action without previous demand and was entitled to possession of the property and damages for the wrongful detention, and that the measure of damages was the value of the use of the property as estimated by the market price of such use during the period of unlawful detention.

Evidence as to Condition of Car Sold.—An automobile was sold for part payment in cash and notes for the balance, the notes being secured by a chattel mortgage on the car. One of the notes being due and unpaid the seller took possession of the car for the purpose of foreclosing its mortgage. In an action of replevin by the purchaser for possession of the car the plaintiff claimed that the seller breached the sales contract in not delivering an automobile in good condition. It was held that evidence covering the repairs to the car for some 18 months after the delivery was inadmissible. The seller only agreed to have the car in first-class shape when it was delivered to the buyer, and not to keep it so, and the trial court should have confined the evidence to this point. Testimony that the car was of a kind and make of little inherent value was held incompetent, and testimony that it was not of the value placed upon it by the seller when making the trade was immaterial.

The buyer gave the seller an order for new automobile parts, which the seller advised the buyer would have prompt attention, and that it carried a full line of the parts ordered, but later it advised him that it could not ship them for three weeks because the factory was not able to supply them sooner. It was held that the seller was not liable because the buyer meanwhile lost possible chances to sell his machine.—Stanley v. Weber Implement & Vehicle Co., (Mo.) 190 S. W. 372.

Automobile Insurance—Larceny by Trick.—The New York Appellate Division holds, Delafield v. London & Lancashire Fire Ins. Co., 164 N. Y. Supp. 221, that a policy insuring an automobile against theft does not insure it against larceny by trick, the commission of which involves as an essential element

Digitized by Google

the deception of the insured by obtaining possession of the automobile through a device of a written agreement to sell it for him, since "theft," as used in the policy, does not include all forms of larceny recognized by law.

Complete Contract of Sale not Variable by Parol Evidence.—The buyer of an automobile signed an instrument covering an order for the car, a list of the equipment included, the price agreed upon, the time of delivery, and the time and manner of payment, and the writing was also signed by the seller. In an action by the purchaser for damages for alleged breach of warranty, the Vermont Supreme Court, Hebard v. Cutler, 99 Atl. 879, held that the instrument evidenced a present agreement of the parties, covering the essentials of a valid contract, and containing nothing to suggest that there were other stipulations which the parties did not intend to include in the writing, so that testimony tending to establish the making and breach of a parol warranty was inadmissible as varying a writing. Judgment for the plaintiff was reversed.

NEW YORK AUTO LAWS.

Relating to the Glare of Headlights and to Driving Rules in New York City.

After August 1 all headlamp glare in New York State must be suitably controlled or deflected so as to avoid any danger of dazzling the eyes of those approaching an automobile from the front. In amending the present laws regarding length of beam or distance at which objects must be illuminated, the newly signed law provides that at a distance of 75 feet directly in front of the car, the beam of light shall not be more than 42 inches above the ground. Further, at a distance of ten feet in front of the lamp, an object ten feet to one side of the direction of the beam must be clearly illuminated. The law applies also to other lights such as windshield spotlights.

Other legislation affecting automobile interests relates to driving conditions within New York City. After August 1, all drivers regularly living or driving within the city must have a separate driving license, which is to be secured from the Secretary of State's licensing bureau at a cost of $1. Professional chauffeurs are not affected by this measure, as they are already required to have a license to drive. Owners, members of their families, all who may properly come under the class of private drivers are required to have such a card, the purpose of which is to register each driver, and by such means to control reckless driving. Drivers from without the city, who have complied with local automobile laws, or those from other States, may drive within the city without such a card for a limited time.

No examination is required to secure a card, and in fact, the secretary's office is arranging to mail out a circular with the necessary forms inclosed that applications may be received and cards issued through the mails.

Keep watch on the spokes of the wheels, especially if the car is an old one. If spokes can be shaken, tighten the bolts on the fingers of the hub. If they are still loose, consult a wheelwright, as your life may be endangered by the breaking of a wheel.

Fire in the Carburetor.

From W. H. Stewart, New York.—When gasoline takes fire it is a serious matter, but the most dangerous accessory to a fire is the one you least expect, namely, panic.

The average person has such an unreasoning fear of gasoline that he loses his head completely. The first few fires will leave one completely unnerved for a time, but after a little experience in fighting them panic disappears and self-control is gained. This does not mean that one should delay or move any more slowly, but should know what to do and do it quickly.

The novice stands aghast as the first burst of flame comes from the carburetor. The experienced man jumps for the nearest preventive. At least one small fire extinguisher should be on every car. The large chemical devices are too bulky and cannot be laid in any position, whereas the ordinary instrument may be stowed away in a small space. The best place is beneath the hood on the carburetor side. This is where the fire starts and may be reached by raising the hood. Some carry them on the running board, but this is objectionable on account of theft liability. If placed under the seat or secured by a lock they are not readily placed in service, and the machine may be badly damaged meanwhile.

Always turn off the gasoline at the tank to stop feeding the flames. Ordinarily there is not more than two ounces in any float chamber and this will not last long. All the parts about the carburetor are metal and not easily harmed. It is well also to use the self-starter to turn the engine. This will draw flames into the manifold. Quite often the whole fire may be extinguished if this is done in time.

A greater danger arises from permitting an accumulation of inflammable material in the drip pan. Once this becomes fully ignited, the situation requires prompt and efficient action. The work of extinguishing should begin right here, leaving the carburetor till the last. Otherwise the burning gasoline at the bottom will continue to ignite that at the carburetor.

So, remember, always start at the bottom and work upward. If there is a flame on the ground beneath the car, use the self-starter with gears in mesh to move to another position. Sand is good if available, but never throw sand on the carburetor or any other parts of the machine. It falls away leaving gasoline free to burn and also gets into the mechanism, doing incalculable harm. On a flat surface sand is excellent, or any other dry powder. Even flour has saved many a home where gasoline has been used carelessly. The old method of covering the fire with a rug or carpet is good, but the extinguisher is better. This covers the fluid with a layer of heavy non-inflammable gas which smothers the flame. Finally, be cautioned never to throw water on burning gasoline. It is heavier than gasoline and tends to spread the flame.

Do not neglect a slight leak in the gasoline line because it isn't leaking very fast. The vapor, being colorless, accumulates without your seeing it, and a disastrous fire may result. If tightening the joints does not stop the leak rub some soap in the threads.

ADVERTISING IS NOT A WASTE.

Figures Show Low Percentages of Costs When Compared With Gross Receipts.

The favorite plaint of the business man who has fallen asleep by the wayside is that advertising is a huge economic waste; that millions of dollars are spent and wasted in artificial attempts to stimulate selling, to the ultimate injury of both buyer and seller. At first glance, and to the man who has not really studied the subject, this argument may appear logical. The only trouble with the logic is that it does not square with the facts. Most people know more things that are not so about this subject than any other under the sun.

"Let us see how much the big advertisers spend," says Alan C. Reiley, president of the Association of National Advertisers, in discussing this matter. "The average man hears talk every day about the millions and millions spent for advertising and he finally gets the notion that somehow or other the buyer has got to pay for it. I wonder if Mr. Average Man ever stops to realize that those millions spent in advertising sell hundreds of millions worth of goods—goods that could never be sold so cheaply in any other way. And it is this immense saving in selling cost that helps to make lower-priced goods.

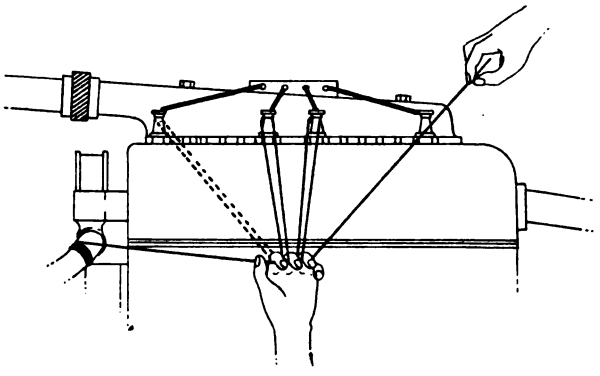
" 'Millions spent for advertising' sounds big, but 'hundreds of millions worth of goods sold by advertising' makes the actual amount spent for advertising look small.

"What is the exact ratio of advertising to sales, anyhow? I am glad to be able to tell the public. The Association of National Advertisers has collected some valuable facts and figures on this subject. Listen to a few of them:

"The advertising of one of the leading paint manufacturers of the country averages 3 1/3 per cent. of their total sales. In other words, for every dollar's worth of paint they sell, they spend 3 1/3 cents in advertising. This is about equivalent to the price of a postage stamp and a cent's worth of paper for every dollar's worth of goods sold. Another big paint and varnish manufacturer spends from 3½ to 4½ per cent.

"Next take clothing. We have obtained figures concerning two of the biggest clothing manufacturers in the country. One spends 1½ per cent.; the other 2 per cent. An equally prominent shoe manufacturer spends 1½ per cent. 'But shoes and clothing are necessities,' you may say. 'How about the luxuries?' All right! Take one of the most popular luxuries in the world—candy. One of the best known candy makers in the country and one of the biggest advertisers spends 5 per cent.

"Then take the big automobile and tire manufacturers with their full page and double page spreads. Surely now the percentage figures will begin to jump. Will they? You will be surprised when I give you the figures for two of the most famous automobile builders in the country. One is 2 per cent; the other is 3 per cent. Also two of the leading tire manufacturers; one spends 2 per cent, the other 2 per cent. And all four rank among the biggest advertisers in the country. These figures are authentic, and when you consider the enormous volume of the automobile and tire business you will see that the small percentages are ample to provide for the wonderful publicity.



"And then we come to the big department stores—where at one time or another every buyer buys. You can see them fairly eating up the newspapers with their big spreads. But if you expect to find big percentage figures here, again you will be agreeably disappointed. The figures possessed by the Association of National Advertisers show that the average department store's advertising does not cost more than 3 per cent of its total business.

"The fact is that the great majority of all nationally-advertised articles—articles which are famous for their quality as well as their immense distribution, belong in the 5 per cent or under class.

"And let this final point be remembered. Even if this advertising represented a direct advance on what the buyer would otherwise have to pay, this would make little difference in the price of the goods. But it does not. And why not? Because advertising is the most efficient method of marketing ever developed by business enterprise—therefore its effect is to decrease and not to increase the sum total of selling cost. This is a simple fact about advertising that every buyer of advertised goods ought to know."

To Test Spark Plugs.

Take about 4 feet of any ordinary thin wire available. Fix it securely to any metal pipe, nut, bolt,

Shorting the plugs.

rod, etc., in metallic contact with the engine. Now, with 3 feet of uninsulated wire in your bare hands you may take a turn round one, two, or three plug terminals, without shock or, indeed, any knowledge of a high-tension current being present, provided you do not actually touch a plug terminal with the fingers. The detail of the arrangement of the shorting wire is made quite clear in the sketch.

This is an ideal method as you "loop" about as you please, and can quite simply pass the wire round, say, No. 1 plug, back round a finger, round another plug, back again round another finger, and obtain any combination without fastening anything, or using any apparatus except the wire.

There is a spice of excitement the first time you try it, as the average owner-driver does not realize that the high-tension current vastly prefers a wire, however small, to himself. The only points for care are not actually to touch a plug terminal and to see that the end of the wire is firmly fixed or bound to the "earth" point, because if it does come off it will prove a valuable advertisement for the heavily insulated variety of fitments usually employed!

Millions Saved for Car Owners.

The full significance of the victory won by Firestone in the Perlman Rim patent case is beginning to be appreciated by the motoring public as well as by the car manufacturer. Through this fight made by the Firestone Tire & Rubber Co. the makers and buyers of automobiles are relieved of an unlooked for and unjust royalty tax amounting to between $1,500,000 and $2,000,000 annually.

It was in February, 1916, that L. H. Perlman in a suit against the Standard Welding Co., had his patent sustained. Up to that time anyone had made demountable rims without restrictions. The Firestone Company, for instance, have been making demountable rims since 1908. The Perlman patent, not issued until 1913, was made operative by Perlman swearing that his invention dated back to 1903.

With the sustaining of that claim the automobile industry faced the situation of Perlman having a practical monopoly on all forms of demountable rims. The factory of the Standard Welding Company was closed and all rim manufacturers notified to discontinue making rims.

At the recent trial Perlman was put on the stand and testified to a completion of his invention in 1903, introducing exhibits and documents alleged to substantiate his claims. During the cross-examination of Perlman, he was led into contradictions and evasions and after several hours questioning very interesting facts were brought out as to his business activities. At the end of the cross-examination, the attorneys for the Perlman Rim Corporation moved to dismiss, thereby shutting off further disclosures by the Firestone Co., which they stated would have been startling. Judge Hand allowed the case to be dismissed, although he stated that it was against his wishes, but he was bound by a long line of precedents.

The thing of importance to car manufacturers and the public is that the Firestone search-light has exposed a scheme which had fastened onto the industry a useless drain of millions of dollars. Needless to say Mr. Firestone is delighted at the outcome of the trial as it puts everybody on an equal footing again where merit and efficiency are the measures by which all will be judged.

Opportunities in Russia.

Russia today is the "land of opportunity" for American manufacturers, because the Russians admire America and like American goods. Freed of oppression, Russia during the next fifty years will rival America in progress, thus opening up an export field of vast proportions. Henry H. Wesener, special representative for the Firestone Tire & Rubber Company, just returned from a year's stay in Russia, thus sums up the commercial aspects of the revolution. Mr. Wesener witnessed the stirring scenes that brought about the downfall of the Romanoff dynasty just before sailing for America. His sojourn gave him opportunity to make a close study of industrial and political conditions in the troubled nation.

He strongly urges American manufacturers to "get busy" immediately in this new export field, providing they are willing to give it the attention it deserves. They should not wait until after the war, he says, because England, France, Sweden and other European countries will have become too firmly intrenched.

"American manufacturers wishing to obtain their share of this vast export business," said Mr. Wesener, "should establish distributing depots, put them in charge of experts from the home factory, men imbued with the home spirit and loyal to the home organization. It isn't essential that he speak Russian because good interpreters are available, but a knowledge of French or German is a great help. They will bring much more satisfactory returns than foreign agents, who are only interested in commissions and take little pride in the product or the organization back of it.

"To obtain the best results at the least possible expense, an exporters' association, controlled by the government if necessary, is advisable. Through it, unscrupulous concerns could be kept out of the field, thus protecting legitimate American manufacturers. Such an association could also supply necessary information, such as proper methods of packing, routing, etc., which if collected by manufacturers individually would be almost prohibitive in cost.

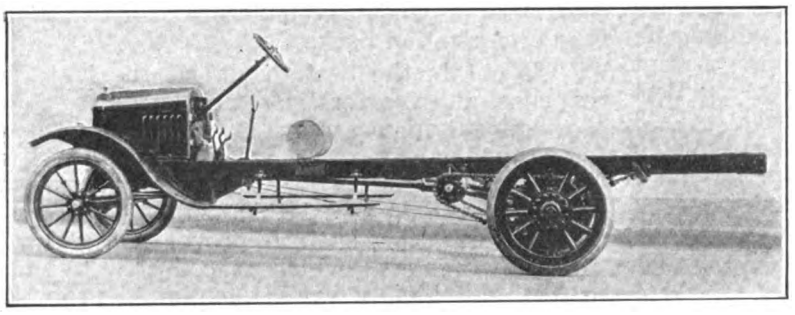
"And last, but not least, the establishment of a strong, substantial merchant marine is necessary to success in the export field. Without it America cannot hope to compete with other countries for the commerce of Russia or any other nation. It behooves every business man to urge upon Congress the necessity for a merchant marine.

"The time may come when this country will be compelled to seek larger export fields or else curtail production at home. The latter course means internal disturbances, labor troubles and a general weakening of our commercial system. Larger export fields mean greater prosperity and a greater nation.

"Never before was such an opportunity offered as there is in Russia today. Russia is just beginning to awaken after years of oppression. Its people have marvelous latent qualities for progress and expansion. It is a country three times as large as the United States, has vast natural resources, such as coal, iron, lumber, petroleum, etc. Eighty per cent. of its population of 175,000,000 people are engaged in agriculture or kindred pursuits. The country offers marvelous opportunities for development along transportation and industrial lines."

Mr. Wesener also emphasizes the importance of liberal investments in entering the export field, American exporters, he says, have been impatient to realize quick returns and have made only small investments.

Don't Postpone Buying.



The business man or farmer who has planned to buy a car, because he needs it in his business, by all means should go ahead with his purchase. If buying is postponed, it is only cutting down the effectiveness of the business concerned. The people who are sitting "tight" are standing in the way of the prosperous financial conditions they are asking for. Money invested now in a motor car will do its good in keeping the wheels of industry moving, and faithfully serve the buyer in time of urgent need. Moreover, prices are likely to be higher.

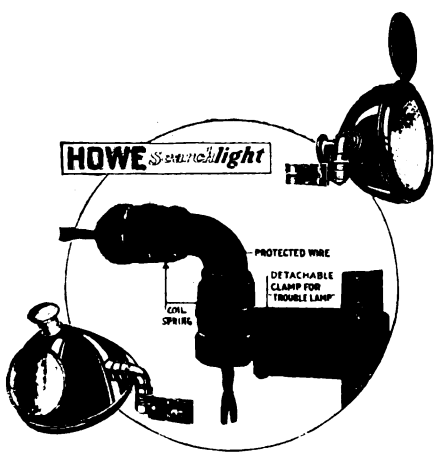
NEW AND INTERESTING THINGS IN MOTORDOM

New Dearborn Truck Units.

Illustrated herewith are two 2-ton Dearborn truck unit attachments, one for a Ford car and the other for an Apperson car, made by the Dearborn Truck Co., 2017 S. Michigan Ave., Chicago. These new units are of strong and durable construction. Ample provision has been made for overloading, the margin of safety being 50 per cent. above rated capacity. Unusual interest in these new units is being shown by Dearborn dealers in all parts of the country and a large number of orders has been booked for immediate delivery, on both types. The two-ton units can be attached successfully to power plants of 40 to 50 horse power; cars such as the Pierce-Arrow, Packard, Peerless, Lozier, Locomobile, Oldsmobile and the larger models of the Hudson and Chalmers and other cars in this class. All of these larger, high priced cars have been built along mechanical lines, that will enable them to give good service for the next five or ten years to come; and a more ideal combination for an inexpensive two-ton truck is hard to imagine than the Dearborn and one of these cars. Other cars that will give good service with the new units are the Overland, Maxwell, Buick, Dodge, Studebaker, Hupmobile, Chandler, Apperson—in fact, any chassis is adaptable.

Dearborn 2-ton unit attachment for Ford chassis.



Dearborn 2-ton unit attachment for Apperson 1913 model.

The new two-ton Dearborn units are built with heavier frame, wheels and general all round heavier and stronger construction to meet every condition of hard service. Their specifications speak truck quality. Five inch channel frame dead axle 2½x2 inches drop forged and heat treated; heavy 3-inch springs, 48 inches long and 9 leaves, with bronze bushings in eyes; additional relief spring over rear axle; heavy truck wheels 34x5 inches, guaranteed hickory spokes and felloes, has 12 2½-inch spokes. Solid rubber tires, 34x5 inches; 1¼-inch pitch Baldwin roller chains and Baldwin steel sprockets. Loading space for 10-foot body.

Howe Searchlight Bracket.

Inasmuch as the idea behind the searchlight is the providing of a freely turning light, it is obvious that the bracket is of primary importance. A chief advantage of the Howe Spotlight is its ingenious patented bracket. This bracket is of the universal joint type and both joints turn at the same time so that the lamp can be moved instantly to any angle. It is directed with very little effort. The driver turns it readily with the one hand as he steers with the other. Although moved so easily, the lamp stays where it is directed until again moved. This is because of the patented spring control. Two coil springs hold the two joints in a firm, even pressure—make it easy to turn, but hold it firmly wherever turned, unaffected by jars and vibration. The Howe Bracket is attached to the windshield frame through the medium of a detachable clamp. This clamp is made in seven styles, one of which is guaranteed to fit perfectly any windshield, whether the post be round, square or oval. Simply loosening the set screw as shown in the picture, releases the lamp and its bracket for use as a trouble lamp.

Stolen Automobiles.

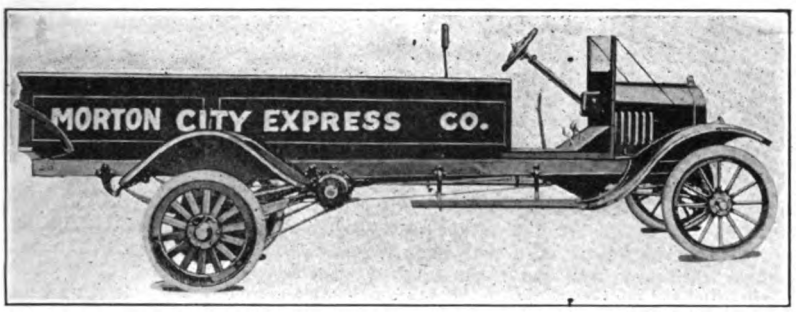
Councilman William Stolte of Cleveland, O., introduced an ordinance, which was passed, to regulate the sale of used cars and parts. It provides that every dealer handling used cars or parts shall fill out a description blank furnished by the department of public safety, which shall list the name and address of persons from whom the car or part was obtained, the time when it was bought and the make, license and factory number of automobiles. These blanks are to be filed with the Chief of Police each day by noon, with the complete list of all the property obtained the day preceding. Maximum penalties of $100 fine and six months' imprisonment are provided. It is believed this ordinance will do much toward clearing up the situation in regard to fences for stolen automobiles, supplies and parts.

Non-Glare Law.

A state headlight law went into effect in Illinois, Sunday, July 1. The chief provision is that no glaring headlights may be used under any circumstances within 200 yards of an approaching vehicle. They must be dimmed or extinguished. Another provision specifies a fine of $10 to $25 for any person under 16 years of age who drives a car, and a similar fine for any one who permits a child to do so.

For a Summer Outing.

What is called the Cozy Camp-mobile is a small, neat looking trailer that is easily hauled behind your car. It contains almost everything to make camp life comfortable and homelike. There is dining room, bed room, kitchen and all the furniture and utensils ready for use and in compact form. Those contemplating taking an outing should address the Bigelow-Waggoner Co., 413 Occidental Building, Indianapolis, Ind., for full description and price of this remarkable outfit.



Phenix Truck Maker.

This is a new device for transforming the Ford chassis, so that it will be adaptable to a truck of 3,000 pounds capacity. The manufacturers call attention to the fact that while the Ford power plant is built to carry the ordinary equipment and body of the Ford passenger car, it is nevertheless capable of pulling many times the weight it will carry, and it is on this basis that the Phenix truck is built. The attachment carries 90 per cent. of the load, while the capacity of the Ford motor can easily pull the load without strain. Readers who are interested should consult the advertisement published by the Phenix Truck Maker, 2337-39 South Michigan Avenue, Chicago, Ill., as this advertisement contains a complete sketch and full description of this device.

Digitized by Google

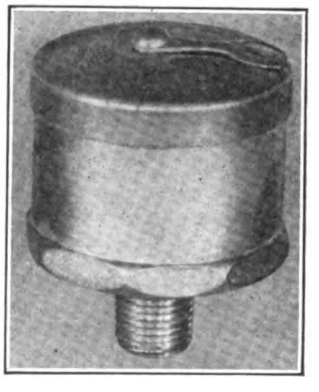
The Truckmobile.

Among other things that will prove an extra impetus to the necessity for good road building from now on will be the ever-increasing use of the motor truck. Speed is one of the big reasons for the adoption of the motor truck in place of the horse-drawn vehicle, and to get the most out of speed requires the country good roads. Motor hauling and delivery is increasing rapidly throughout the country; and what is decidedly important to the good road movement, the motor truck is gaining particularly well of late in the rural districts, even in those more isolated sections that are isolated chiefly because of the barrier of poor roads. Everybody knows the reliability of the Ford power plant. Everybody knows its simplicity. If there should be repairs to be made they can be made in a hurry. Take such a power plant with a truck attachment such as the Truckmobile and you have a truck that

Truckmobile attachment for Ford cars.

carries with ease a ton and-a half load. The 133 inch wheel base of the Truckmobile (which by the way is five to eight inches longer than any other converted truck) and the extra wide frame permit the use of a wide variety of bodies. One day you can use the Truckmobile for some particular and distinct kind of load and the next day you can use it for an altogether different kind. In other words you have a flexible truck service in a high degree. In military use, this would be extremely valuable, as it is in many lines of business. The oversize dimensions also make for easier riding and better control of the machine. Simplicity makes for strength. That is why the key-note of Truckmobile design is simplicity throughout. The simplicity of Truckmobile construction starts right with the very attaching of the unit to the Ford. Any two men who can handle a hammer, wrench and drill can do the job in five or six hours. But the big feature of Truckmobile engineering is the spring construction, and the big thing about this is the suspension of the side springs from the lower side of the frame. Truckmobile springs are not suspended at the side of the frame as in other attachments, but interposed between frame and axle. A word or two of explanation will make it easy to see the reason for this. In trying to lift a weight above your head do you hold your arm out from your side and lift the weight obliquely upwards, or do you thrust your arm directly upwards? Of course you do the latter—and there you have the reason for the Truckmobile spring suspension. By keeping the spring directly under the frame of load, the strain on springs and rests of chassis including bearings is far less than it would otherwise be. Made by the Commercial Truckmobile Co., Chicago, Ill.

Fuel Economizer.



A new gasoline economizer that is not an experiment but a demonstrated success, is made by the York Carburetor & Auto Accessories Co., Inc., 681 Woodward Avenue, Detroit, Mich. The manufacturers are so very sure that this device will result in a great saving of fuel that they promise to guarantee it and return the money for the purchase price if not satisfactory. The firm thus takes all the chances themselves. The device can be installed without making changes of any sort. The cost is so low that no one need consider it anything but a real economy.

A New Ford Accessory.

The Burn-Oil Device Company, Peoria, Ill., claims great saving in fuel for Ford cars by the using of a kerosene attachment. They have scores of letters confirming this, among them quite a number stating they had been able to run their car 35 miles on a gallon of kerosene. In these days of the high cost of fuel it is the duty of everyone to maintain their car at as little expense as possible, and there should be a big sale for this new fuel saver.

An Automatic Oil Cup.

A decided innovation in an automatic oil cup has recently been patented which will be of interest to car manufacturers and the trade in general. In appearance it resembles an ordinary oil cup, but the walls are lined with felt and in the center of the cup is a hollow standard upon the top of which a steel ball vibrates with the movement of the car, carrying the

Automatic Oil Cup.

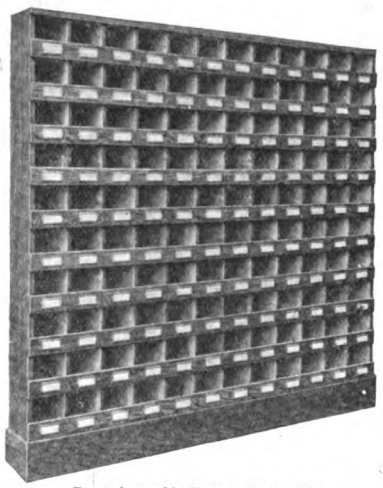
oil, which is drawn up through the felt by capillary attraction, across the top of the hollow standard, the vibration being sufficient to take the oil in such quantities as may be determined by increasing or decreasing the size of the ball. The cups are made in various shapes to take the place of grease cups as applied to automobiles. One of its strongest features is the fact that it ceases to feed oil the moment the car comes to a stop, so that one filling of oil will last from 3,000 to 5,000 miles. It is claimed that spring bolt replacements will be eliminated and with perfect, efficient oiling, any car will have much longer life than heretofore. Distribution will be made by D. S. Hickey, Jr., 40 Iffley Road, Boston.

Prest-O-Lite Welding Apparatus.

The Prest-O-Lite Company, Inc., Indianapolis, Ind., have issued a new catalogue of their apparatus for oxy-acetylene welding and cutting. It is well illustrated and extremely apprehensive. Those interested in welding and cutting will find it useful for the information it gives.

The Liberty Light Flag Holder.

This is a flag holder for holding the flags of the three principal allies in the great war—the United States, France and Great Britain. The attractive feature of this flag holder is that it is illuminated from below, so that at night the effect is very beautiful. This will be a patented feature, as a patent has already been applied for. The illustration will give readers an excellent idea as to the appearance of this device and the method used for illuminating the flags. A 6 or 12 volt lamp is furnished with the flag holder for illuminating purposes, and the whole outfit will appeal to a very large number of car owners. It is also a quick seller for dealers and agents, and any who are interested—whether dealers or owners—should write for prices and full particulars direct to the manufacturers, the Utilities Sales Association, 607 West 43rd Street, New York City.



A Simple Vulcanizer.

You can do your own vulcanizing with the Superior Vulcanizer, made by the Superior Vulcanizer Co., 16A Fulton Avenue, Rochester, N. Y., and be independent of anyone. It is guaranteed to work satisfactorily, and costs but a song.

Digitized by Google

For Keeping Stock.

The Accessory and Parts Stock Bin illustrated herewith, meets a long felt want for a convenient and economical equipment for handling stocks of valves, valve springs, bolts, piston rings, bearings, bearing cones, grease cups, etc. It is not only attractive in appearance and well made, but it costs little. It contains 120 compartments, 6 x 8 x 10, which will

Contains 120 Compartments.

care for practically all of the ordinary sizes of accessories and small parts around a garage. The front partition and ends of the bin are genuine oak, with a light grained finish. The back is of sheet steel. Each compartment bears a metal card holder for indexing its contents. It makes an attractive, serviceable and economical equipment. Price, $25.50. Manufactured by the Hobart Brothers Co., Troy, Ohio.

A New Car to Appear.

The Wolverine Motors, Inc., has been organized at Kalamazoo, Mich., for the purpose of manufacturing a high grade, four cylinder speed roadster and four passenger touring car. The capital stock is $125,000, which will soon be increased. The new concern intends to get out several demonstrators for 1918 and in the meantime will secure a permanent factory so as to be ready for active production for the 1918 market. The cars will sell for $3,000 and up and the number produced will never be in excess of 1,000 annually.

The Hoosier Sub-Carburetor.

This device if used on any car will increase its flexibility, make it start easier, and will prevent carbon. The manufacturers offer the purchase price back in 30 days, if it is not satisfactory. They have sold 4,000 already, and among these purchasers more than 3,000 have given testimonials without solicitation as to its merit. If you are an automobile dealer you should at once communicate with the manufacturer, the Hoosier Sub-Carburetor Co., Indianapolis, Ind., and get the agency in your territory. The demand will be very large for every user of it will tell his friends and they, naturally, will want something of this sort, which gives from 30 to 40 per cent more mileage, more power, and more speed to their cars. It can be installed in a very few minutes, and you will be surprised at the effect it will have on the running of your car. One man says that after he put one on, he closed his needle valve nearly one-half turn and the engine had more power than it ever had before.

A Handsome Ford Radiator.

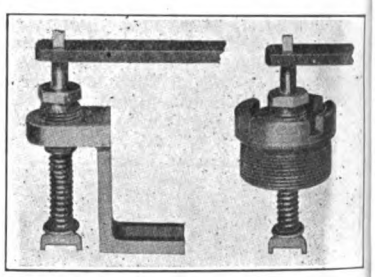
The Radiator Sales Co., No. 8 Mt. Elliott Ave., Detroit, Mich., manufactures a radiator for Ford cars that is as much ahead of the original one when the car leaves the factory, as a dress suit is superior to a pair of overalls. The price is but $27.50, the hood is stream lined, and everything is complete to install on the Ford car. In ordering state the year in which your car was built, and whether nickel or black enamel is desired. The same firm has a limited number of "490" Chevrolet radiators, which they will close out for $20 each, as long as they last.

A Complete Comfykit.

What is called the Nathan Comfykit which was especially designed for soldiers and sailors is now to be sold to the general public, and is especially desirable for automobile tourists. It contains about everything one may need for the toilet and is being put up so as to take little space, and it is easily accessible. It makes a fine and appropriate gift to the young man who goes to sea or in the army, and the price is very low considering the material with which it is made and the various articles it holds. There are buttons, a mirror, darning cotton and needles, tooth brush and tooth paste, and an emergency case for accidents, a soap box and a pocket for stationery, a box for extra razor blades, etc. For full information address the Nathan Novelty Mfg. Co., 84-90 Reade St., New York.

New Welding Torch.

The Bishop-Babcock-Becker Company, Cleveland, O., has marketed a new welding torch as illustrated herewith. This torch has a single tube and it is, therefore, possible to do the lightest and heaviest welding by simply changing the tubes. The manufacturers state that when the proper gas pressure is obtained



Improved Welding Torch.

it is practically impossible for this new torch to back-fire, regardless of the size of tip used. This feature will be appreciated by every user, as it not only saves a great deal of time but eliminates considerable trouble. Attention is called to the fact that while this welding torch is durably constructed it is light and easy to handle, being designed to fit the hand. It is said that the torch is simple to operate and skilled labor is not required. The illustration shows that the valves are conveniently placed below the handle, and a proper mixture is secured without difficulty. The manufacturers, whose general offices and factories are located at Cleveland, Ohio, will be glad to give further particulars, and will send a complete catalog describing their oxy-acetylene welding and cutting apparatus upon request.

A New Valve Grinder.

The main thing in grinding a valve is to do it in little time, and do it absolutely right, whch can be done with the Kandikid Valve Grinder. It is simple, can be very easily handled, and it will grind the valve of a 4 or 8 cylinder car almost as quickly as it would grind the valves in a 1 cylinder car. The illustration will give some idea of the valve grinder and the way it works, but it can give little information as to its superiority. In the new valve grinder now first on the market all its previous merits as relating to its use on motors with removable spark plug bases (port caps),

The latest valve grinder.

have been retained, and the inconvenience of carrying a pressure block for each size and thread of port hole has been eliminated by the substitution for a spark plug, of a block which has a duplicate of the threaded part of the spark plug. This same block, transferred to the Z-shaped support, acts in the same manner there in putting the actual required and definite pressure on the two surfaces composing the valve, the receiving hole in the support having been designed especially for this specific purpose. The valve grinder is to be marketed by W. C. Brown, Niles, Ohio. It is expected that the delivery of machines will take place soon after this issue of our magazine appears.

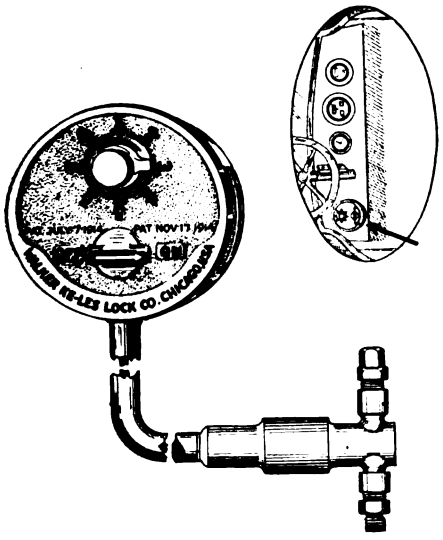
Women in Factories.

Planning to meet the labor shortage which will be produced by a prolonged war, the motor car industry is beginning to regard women seriously for factory work. At present approximately 3,000 women are being employed in the factory of the Chalmers Motor Co., the Aluminum Castings Co., Morgan & Wright, the Maxwell Motor Co. and the General Brass & Aluminum Co. The Chalmers Motor Co. is making a very extensive experiment and has placed women on drill presses, bench machines, milling machines, assembling machines and inspecting and is also using them in the foundry. Various manufacturers, now figuring on the employment of women, contemplate placing them in such occupations as sorters, counters, inspectors, sweepers, cleaners, punch press operators, screw machine work, threading and tapping screws, bench assembling and core making.

The Latest Tire Improvement.

In the old bicycle days Palmer tires were universally considered the best. They were used by all who wanted durability and easy running. Mr. Palmer has probably made more tire improvements than any one else in the business. He now manufactures a safety-cord inner tube, which practically does away with

Digitized by Google



blow-outs, and gives the tire unusual resiliency. All first-class dealers are anxious to get these Palmer tubes to sell and the success they have had with them was a surprise even to themselves, but they want more dealers of this same type and they will back up the efforts of such salesmen with strong and convincing advertising, and thus make the sales large and continuous. This tube is made by the Palmer Tire and Rubber Co., St. Joseph, Mich.

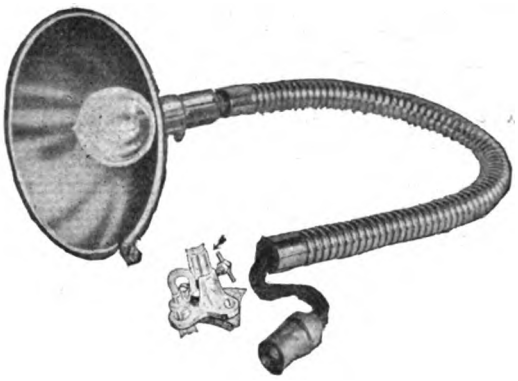
New Gas Delivery System.

The Allen Pressure System Co., Inc., 20 West 61st Street, New York, have placed upon the market a Gasoline and Oil Storage and Distributing System, which eliminates both waste and guess work. It is fireproof, simple, and approved by the Board of Fire Underwriters. They also make a meter which shows at a glance the exact, individual quantity drawn off, and the total amount used. Attractive literature will be mailed upon request and agencies are advised to get in on the sales of this system before it is too late.

A Real Auto Lock.

The auto thief is becoming more bold every day. He plys his trade in the country as well as in the city. It is a good plan to lock the door of the barn before the horse is stolen, and likewise it is wise to lock the automobile before some thief gets it. If you use the Walker Ke-Les lock your car will be absolutely safe, and the price is only $10. You can probably secure one of these locks at any garage or automobile store

A safe lock.



and when installed on your car one small turn of the wrist makes it safe. It locks a lock quicker than you can find your key. It is guaranteed absolutely, and with the three number combination you are the only one who can start your car. There are more than 87,000 changes to this combination. For full information, address the Walker Ke-Les Lock Co., Chicago, Ill.

New Stanwal Brake Lining.

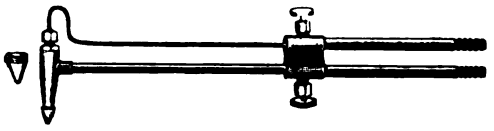
The Standard Woven Fabric Co., Walpole, Mass., has announced a new brake lining material named Stanwal. This new material is impervious to oil, grease, gasoline, water or any foreign substance. The primary base of Stanwal is brass wire covered and protected by a special fabric, specially treated and proof against frictional heat. The company will continue the manufacture of Multibestos lining and clutch facings. Stanwal is also used for clutch facings, friction and insulating tapes, matting, etc. Before introducing Stanwal, it was subjected to a most exhaustive test, the results of which showed the material to have a uniform coefficient of friction of .40 as against .37 in the average brake lining material.

Improved Spotlight.

An extremely ingenious spotlight has just been placed on the market, being manufactured in Los Angeles, Cal. This spotlight incorporates a number of novel features of particular value to motorists and motor cycle users. Although made in three types, the leader of the line is the "Flexarm" model. Instead of the conventional bracket being used in this model, a flexible metallic tubing, similar to that used for speedometer cable-casing, supports the lamp. The advantages of an extremely flexible support such as used here becomes apparent at once. The light may be thrown instantly in any desired direction, forward, backward, up or down, with the very slightest effort of the driver. The manufacturers state that the lamp will stay in any desired position when driving, except over extremely rough roads, because of the spring action of the flexible tubing arm which can be twisted to any desired tension to overcome vibration and shaking. The Kaybee Spotlights are all of the concentrating type; that is another feature of the construction. By means of exclusive construction methods, it is said that they give more concentrated light with less glare or diffusion of rays than that heretofore obtainable. The effective light range is also of greater length, from three-quarters to one mile. A thumb switch is conveniently located just in back of the reflector. Connection of the flexible support is made at the dash by means of a small socket connection and bracket combined, which is quickly installed. These lamps are manufactured and distributed by the Accessories Supply Company, Henne Building, Los Angeles, Cal.

Kaybee Spotlight and Flexible Support.

The Right Service.



Garagemen have a great opportunity to co-operate in the popularizing of tractors this summer, according to W. C. Giberson, manager of the J. I. Case Threshing Machine Co., at Kansas City, Mo. This company has had few calls for service, though it keeps service men out. It sends complete instructions by which the owner can learn his tractor by heart, and know exactly what is the matter with it if anything goes wrong. It is natural, however, that this summer, many inexperienced operators will be called to run tractors—any tractor—and that there may be more or less demand on the local garagemen for service. "The garagemen can serve the industry in a very valuable way, if they go to the farms on such calls, with the desire to boost, rather than with any spirit of criticism," says Mr. Giberson.

New Detroit Electric.

A new Detroit electric is being produced by the Anderson Electric Co. It has a Springfield type body; side steering lever; or steering wheel if desired at an additional cost of $30; body in cobalt blue; wheels, optional color; Goodrich Silvertown tires, 33 by 4½; Detroit battery, 42 cells, 13 plate; 25 m.p.h. maximum speed; mileage capacity 65 to 100 miles, depending on road conditions. Price, $1,975.

For Battery Repair.

With the Turner Lead Burning Outfit No. 7, you are able to repair storage batteries quickly and efficiently. The apparatus is adapted to nearly every condition of the shop, at a reasonable cost. The use of oxygen and acetylene for lead burning has been adopted by many of the larger firms doing this class of work due to the fact that our torch is so constructed that the flame can be controlled

Turner Lead Burning Outfit.

to any size and temperature desired. The construction of the torch is such that the pressure from air or oxygen will siphon and thoroughly mix the gases. It can be used with oxygen combined with either illuminating gas, acetylene or hydrogen; or with air pressure combined with either illuminating gas, acetylene gas or hydrogen. It is specially adapted for brazing and welding. The price is very low. Manufactured by The Turner Brass Works, Sycamore, Ill.

Tires for Ford Cars Only.

Included in the various buildings being erected at the River Rouge by Henry Ford will be a very large unit devoted to tire manufacturing. Tires made in this factory will be manufactured exclusively for Ford cars.

Keep Your

Johnson's Carbon Remover

Cures 80% of Engine Trouble

That knocking in your engine—the difficulty you have climbing hills—poor acceleration—lack of power—pre-ignition—noisy motor, are all caused by carbon.

Put New Life in Your Engine

with Johnson's Carbon Remover and it will run like it did the first 500 miles—quietly and full of "pep." No matter how choked up your motor may be, Johnson's Carbon Remover penetrates and softens the carbon. It then burns and powders and is blown out through the exhaust.

You Can Do It Yourself

Five minutes' time and no labor required. Simply lift the hood and pour an ounce of Johnson's Carbon Remover into each cylinder through the petcocks or spark plug openings. Go to bed—get up in the morning and drive a perfectly clean engine.

Use It Every 1000 Miles

If you will use Johnson's Carbon Remover at regular intervals, giving carbon no chance to accumulate, you will automatically eliminate most valve trouble and your engine will always be at its highest efficiency.

Pints $1.00

Johnson's Stop-Squeak Oil

Has the Remarkable Property of Seeping Rapidly Between the Spring Leaves

and to the furthermost wearing points and it there becomes a heavy-bodied lubricant.

The irksome task of jacking up a car, prying apart the spring leaves and lubricating them is forever done away with. You, yourself, can now keep your springs thoroughly lubricated at all times. All you need is Johnson's Stop-Squeak Oil.

Make Your Car Ride Easily

Johnson's Stop-Squeak Oil is a simple remedy for hard riding cars. Instead of bumping over the road, you fairly float along if your springs are lubricated so you have spring action. Johnson's Stop-Squeak Oil reduces the liability of spring breakage.

For Squeaks of All Kinds

Johnson's Stop-Squeak Oil will remove squeaks of all kinds—in springs, shackle bolts, body, fenders, top, etc. Just locate the squeak and touch it with Johnson's Stop-Squeak Oil.

Johnson's Prepared Wax

Now Made in Liquid Form

so that it may be more easily polished. Johnson's Prepared Wax ***Liquid*** is the same as our Paste Wax except that it is a Liquid.

Johnson's Prepared Wax ***Liquid*** will prove a joy to the thousands of automobile owners who prefer a wax polish on their cars but are not inclined to spend the time or effort which Paste Wax requires.

Apply with Cloth, Brush or Spray

Johnson's Prepared Wax ***Liquid*** is very easy to apply and polish—but little rubbing is necessary. You can go over a good-sized car in half an hour. It preserves the varnish and protects it from the weather, adding years to its life and beauty. It covers up mars and scratches—prevents checking and cracking—sheds water and is absolutely dust-proof.

Quarts $1.20

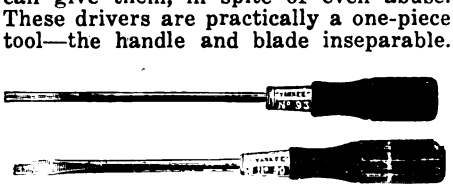
Testing Ford Coils.

There has just been placed on the market by the Ballman-Whitten Mfg. Co., 2867 Gravois Ave., St. Louis, Mo., a device for testing Ford coils, which sells to the trade for $5.10. This Tester consists of a wooden base upon which is mounted a low reading ammeter, receptacle contact springs in which to place the coil to be tested and adjusted, a couple of binding posts for connecting on a 6-volt storage battery or four dry cells, an adjustable spark gap and a switch for making or breaking the circuit. The coil to be tested is slipped into place and a battery is connected on to the binding post provided on Tester base. The switch is then closed and the ammeter should give a fairly steady



B-W Coil Tester, with coil in place.

reading of about 1½ amperes with a continuous flow of sparks across the spark gap. If the current is lower than 1.2 amperes, then the vibrator spring on the coil is weak and should be strengthened as follows: Remove the cross piece that carries the adjustable contact. Now note the distance that the vibrator spring stands away from the coil head. Increase this distance slightly by bending the vibrator spring away from the coil head. Now replace the adjusting cross head and the current will have increased as well as the stream of sparks. If the current is higher than 1.8 amperes, then the vibrator spring is too strong and stands too far away from the head of coil. In this case the vibrator spring should be bent inward.

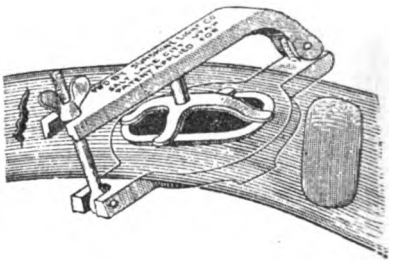
Screw-drivers You Can Rely On.

The manufacturers of "Yankee" Tools, recognizing the usefulness of the rigid blade screw-driver, have produced a plain screw-driver with rigid blade that is superior in its way to the ordinary driver. Plain screw-drivers have handles that won't work loose. They can't work loose in spite of the hardest usage a man can give them, in spite of even abuse. These drivers are practically a one-piece tool—the handle and blade inseparable.

Superior Screw-drivers.

The ingenious little "Yankee" device locks the steel shaft firmly in the hardwood handle so that it never lets go its grip. And these handles are specially shaped so that the mechanic can get a firm hold upon them. The "Yankee" Plain Screw-driver comes in two styles: No. 90, the standard style, has fourteen different sizes or length of blades, running from the little two-inch fellow that you can slip in your pocket, up to a 30-inch blade—the largest screw-driver ever made. The No. 95, cabinet style, is made in eleven sizes—from 2½-inch to 15-inch length blades. In other words, no matter what your particular liking in size or shape of rigid blade screw-driver is you'll find among these twenty-five different sizes one that is going to exactly fit your needs, your requirements and your particular taste in drivers. Made by North Bros. Manufacturing Co., Philadelphia, Pa.

Heating the Fuel.



At the present time, not only on account of the high cost of gasoline, but the shortage of the supply, every private user is interested in trying to devise means to increase the efficiency of this particular commodity. Numerous inventions have been tried out to increase mileage or efficiency, also with a view of decreasing costs. Various devices have been used, a great many of them along the same general lines, applying heat to increase vaporization. The use of heat has been attempted, in different forms, either water jacketed manifolds, hot air attachments to carburetors, electric attachments, etc. Therefore they all acknowledge by their efforts that heat is the solution, provided it is properly applied. The first point of interest is, where to obtain the heat and can it be relied upon to give a supply at all times. There is a supply in the exhaust manifold, it is of high enough degree to produce the desired results. The next thing is to utilize it and apply it where it will act upon all of the gasoline before it enters the intake ports of the motor. The Hot Spot Heater is attached in such a way that every particle of gasoline must be influenced as it passes through the intake manifold, as it must strike upon the hot spot, and as the heat is circulated through the hot spot, this circulation being caused by the back pressure from the muffler, and as the heat is given up at a predetermined point, this being accomplished through the method of space restriction at the end of the hot spot, which is inside the intake manifold, through friction, this heat is intensified. There are 1,400 degrees of heat in the exhaust manifold and the natural radiation, in carrying this heat to the Hot Spot Heater, will reduce the intensity but will still leave sufficient to answer the purpose, tests having proven that from 500 to 650 degrees Fahrenheit will actually be delivered at the end of the hot spot, or a surplus of above 100 degrees Fahrenheit more than is necessary to entirely vaporize the gasoline. The Hot Spot Heater is being marketed by the Economizer Sales Co., 2838 Michigan Ave., Chicago.

Piston Ring Directory.

Probably the most complete reference book ever published by a manufacturer for free distribution among Dealers and Mechanics, has just been issued by the Burd High Compression Ring Company, piston ring manufacturers, Rockford, Illinois. This directory is an invaluable source of information for the mechanic and contains data not only on Burd high compression piston rings, but on piston rings in general, their proper fitting, their installation, their lapping and everything connected with this branch of mechanics. The book contains 264 pages. is attractively bound and should be in the hands of every garage man and dealer for information that cannot be obtained anywhere else in such a complete and comprehensive form. It will be mailed free upon request to any member of the trade, using his stationery or enclosing his business card.

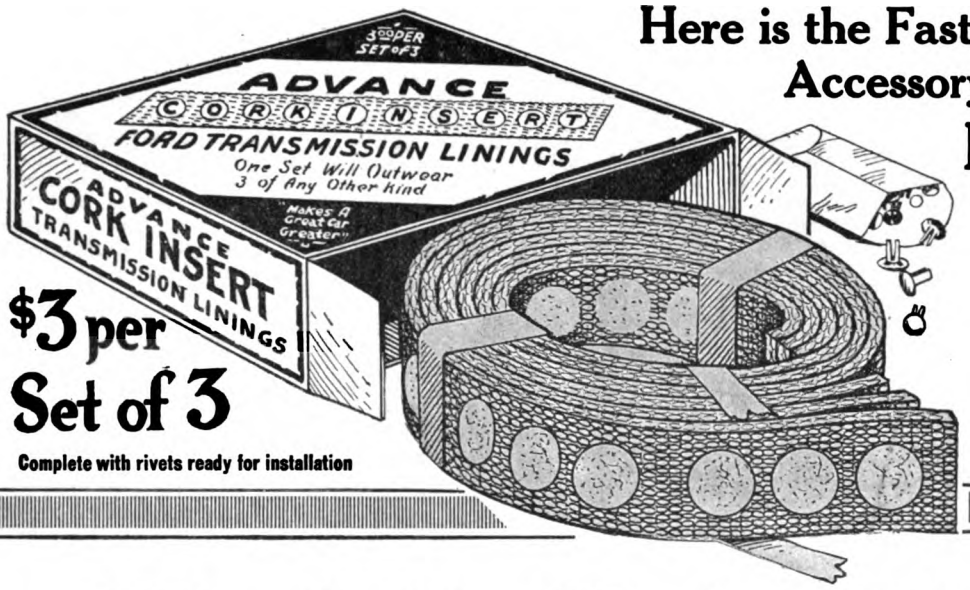
Lifts the Irk from Puncture Work.

This Super-Vulcanizer will vulcanize a patch quickly and permanently on any automobile or motorcycle inner tube in five minutes without the use of cement, gasoline, alcohol, acid or blaze. Cannot overcure. Will not blow out in the wind. The fuel is a harmless combustible preparation contained in a pan. The vulcanizable material is specially prepared raw

Super Vulcanizer.

rubber furnished on the reverse side of the pan. When you apply the patch just ignite the heating substance with a match, which is sufficient to cure the raw rubber. In five minutes you have a perfect, permanent repair. Discard the pan and ashes, then tube is ready for instant use. No experience necessary. If you can light a match you can operate it. Manufactured by Sunshine Light Co., Inc., 70 West 4th South St., Salt Lake City, Utah.

Two New Auto Specialties.



The Apco Mfg. Company, formerly the Auto Parts Company of Providence, R. I., has brought out two new specialties for the Ford car. One of these should appeal to those owners of Fords equipped with the horn button located on the steering column, as the new horn button attachment is attached to the center of the steering wheel where it can be operated without the driver removing his hands from the wheel. The Apco horn button attachment can be installed in a few minutes, comes with the necessary wiring and retails at 25 cents. The tapered filler tube of the Ford car is not adapted to the usual flag holder, and to meet the demand for a three-flag holder the company has brought out a design that displays the flags to a good advantage as the staffs are crossed. The holder is easily attached, becomes a permanent fixture, is finished in black enamel and retails at 25 cents.

Overhanging Loads.

The Hoosier Motor Club has induced the common council of Indianapolis, Ind. to pass an ordinance providing a heavy fine for the driving of a vehicle after sunset containing a load that extends over the bed of the vehicle five feet or more without having a red light attached at the end of the protruding load. The club had compiled statistics to show that many accidents have resulted from motorists colliding with objects extending over the beds of vehicles.

Here is the Fastest-Selling Accessory of 1917, Dealers!

$3 per Set of 3

Complete with rivets ready for installation

They Make the Ford Brake BRAKE

YOU know how the Ford jumps when it starts, and jerks when it stops — how it shivers and jars every time the brake goes on. Here is something that puts velvety smoothness in the Ford Transmission, so that it goes into low or reverse like a high-priced car. It starts gliding to a quiet stop at the first touch of the toe on the brake. No more clatter, no more jar — regular big car stuff.

ADVANCE
CORK INSERT

TRADE MARK REG. COPYRIGHTED 1917.

TRANSMISSION LININGS FOR FORDS

They STOP the Grabbing and Slipping

Into expensive, imported transmission fabric are inserted circular pieces of cork, slightly thicker than the fabric itself. These cork surfaces engage the brake drums immediately when the pedals are pressed, due to the high coefficient of friction of cork and steel. **Ordinary transmission fabric becomes glossy and hard** and does not grip unless an excessive amount of pressure is brought to bear. Then it suddenly grabs and slips—and that's what causes the jars and the mechanism-killing vibration.

The corks in Cork Insert Linings eliminate the slipping, the jarring, the vibration, of starting and stopping. They also add wonderfully to the life of the linings. The corks wear very slowly—never become hard or glazed—hold their place in the fabric throughout the long wear and do their work to the very last.

Advance Automobile Accessories Corp.
Dept. G5-1 56 E. Randolph St., Chicago

That's why Cork Inserts outlast two to three sets of ordinary linings.

Get Cork Inserts Now

Cork Inserts are being advertised to your trade in the Saturday Evening Post and leading trade papers. They are selling by the thousands. Your customers know about them and are ready to buy as soon as you are prepared to sell them. It's harvest time right now.

Cork Inserts are sold in handsome two-color packages, complete with rivets for installation. Use the coupon and send your order today for Cork Inserts. Your Jobber will get full credit.

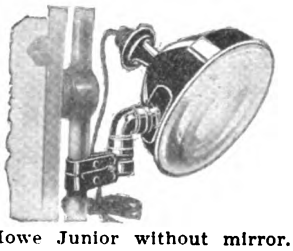
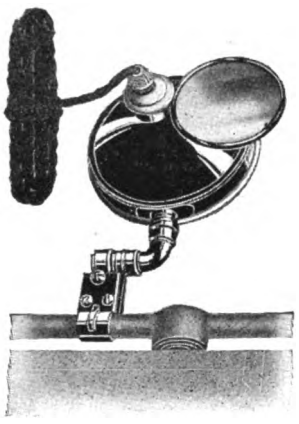
Standard Norma Ball Bearings.



The Norma Company of America, 1790 Broadway, New York, in consideration of the Washington Convention of the Society of Automotive Engineers, issued a special folder under the title "Norma"—In the National Service." In very brief paragraphs it refers to the almost universal standardization of magnetos and lighting generators on "Norma" Ball Bearings in the fields covered by the combined societies—automobiles, trucks and motorcycles; motor boats; aeroplanes; gas engines and tractors. Without specific reference in the text to war time conditions, a martial atmosphere is given the folder by the character of the pen-and-ink illustrations.

Tightens Auto Wheels.

Out in Modesto, California, they are making a preparation that solves the problem of many motorists. All car owners can remember the time when one of the wheels was so loose that only a kind providence saved the occupants of the car from injury. The Liquid Wheel Tightener Company is now making and marketing a preparation called Spoktite, which, it is claimed, will prevent wood treated with it from shrinking. Hot, dry weather has a sure effect on the spokes and felloes of wheels, and in fact, on anything made of wood. Floors, tool handles, implements, all warp and shrink out of shape. Everywhere that a firm union is necessary and is dependent upon the close-fitting of one or more wooden parts for its durability, there is great danger of its failing in its purpose. Spoktite will repair all such breaks. An axe handle can be replaced and a permanent joint made with the application of Spoktite. Some wheels can be taken from the scrapheap and a good repair made with this liquid tightener. It swells any wood to which it is applied and will remain on the job for a long time. The Liquid Wheel Tightener Company, of Modesto, California, will gladly answer any questions about Spoktite or send a sample if desired.



Rear View Spotlight.

Appreciating the demand for a spotlight with the famous Howe spring controlled bracket in a low priced model, the Howe Manufacturing Company has added a new model called the "Howe Junior No. 15." It has a four-inch rear view mirror and sells for $4.75. The same lamp without the mirror sells at $4.

Howe Junior without mirror.

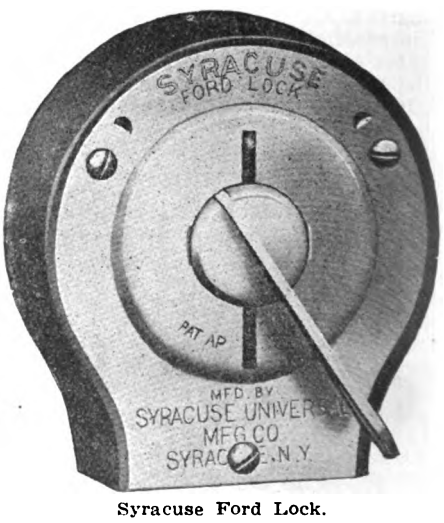
The Howe Spotlight is unique in that it provides without extra charge, two-piece detachable clamps for attaching the lamp with its wonderful bracket to any windshield post; round, square or oval. Jars and vibration do not affect the position of the lamp. This means that it is very readily attached to any car. Loosening one set screw, the clamp detaches and the spotlight can be used as a trouble lamp. The Howe Junior is a very fine appearing lamp. The finish is as good as the car. The principal difference between it and the larger and more expensive models of the Howe is that it is single shell, and does not have the cord concealed inside the bracket. Dealers,

With mirror.

garage owners, and car owners will be interested in a new leaflet describing all of the Howe Spotlight models, which can be had free of charge by writing the manufacturer, mentioning this journal. Address Howe Manufacturing Company, 1732 S. Michigan Ave., Chicago.

Tuthill Spring Co. to Use Gas Furnaces.

The Tuthill Spring Company of Chicago are now operating, full time, a total of fifty-two fuel oil furnaces in their forging and heat-treating departments. Owing to the excessive price of fuel oil, they have been conducting a series of experiments on a new type of gas furnace, which so far indicates more perfect combustion at lower cost than has been possible heretofore. The demand for automobile pleasure car and truck springs has far exceeded the capacity of the Tuthill Plant, and no more contracts will be accepted for 1917. A bulletin recently posted at the Tuthill factory, over the name of F. H. Tuthill, President, is interesting because of its reflection of the spirit of the times. It reads as follows:



"War necessities must have first call, that is, springs required by our government come first, but ways and means must be found not to side track ordinary contracts or orders or general replacement business. Our ability to meet increased demand by the maintenance of maximum production will be a test in which we must all take part. If this company can so eliminate wastes, as to increase its capacity to meet the demands of old customers, and also meet and possibly anticipate demands from our government, while at the same time coping with problems of raw material shortage and labor difficulties, then we shall be able to go through to peace without noticeable disturbance to the industries which we assist."

Chalmers Six Does Locomotive's Work.

The Chalmers Master Six is in regular service as a locomotive over the Warner & Webber Falls Railroad Company of Oklahoma. This railroad runs the 12 miles between Warner and Webbers Falls. The Chalmers pulls two freight cars over the two and one-half per cent grade with loads from 5,000 to 25,000 pounds three scheduled trips every day and sometimes several extra trips. Carrying these loads it takes from 30 to 45 minutes to cover the 12 miles. It is the regular Chalmers Master Six in all respects except the flanged metal wheels to fit the rails. The car can be converted into an automobile for road use in 30 minutes. It was driven 20,000 miles before being put in service as a locomotive. This railroad was the only one running between these two towns and after it failed the Chalmers Master Six was substituted. The car carries 7 passengers in addition to hauling two freight cars. The passenger fare is 50 cents one way. S. R. Threlkeld, President, General Manager and Chief Engineer of the railroad, says that he has never had one minute's trouble with the Chalmers "locomotive" in the months it has been in service. He has not even had to take out a spark-plug and frequently remarks that the Chalmers is a fine car. "They must certainly put good material in 'em. We get from 8 to 12 miles on a gallon of gasoline over the rails with this sturdy Chalmers locomotive."

Lock Your Car.

Every owner of a car, of course, knows how important it is that his car should be locked when left even for a brief period. There are gangs of organized automobile thieves all over the country stealing cars wherever they can when left unguarded and not properly locked. It is not very long ago since a $6,000 car was stolen in this city while the chauffeur was running up the steps of his employer's house to notify him that the car was at the door. Just as the chauffeur's back was turned, the thief jumped into the car and got away with

Syracuse Ford Lock.

it. The Syracuse Universal Manufacturing Company, Syracuse, N. Y., have brought out a good lock especially for Ford cars which sells at a price which brings it within the reach of everybody. See accompanying illustration. They say it is absolutely burglar proof. It can only be turned by the keys accompanying each car. If you are interested, send for descriptive circular giving further particulars and prices. Do not permit your car to remain unlocked when left standing even for a minute, or you may lose it sometime or other.

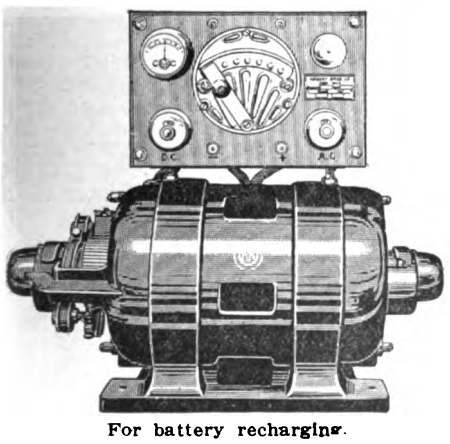
Auto Light Deflector.

The Art Metal Mfg. Co., Cleveland, O., has put on the market a device that fully eliminates the glare of atuomobile headlights, and it costs but $1. It is sold with a money back guarantee, and dealers and garage and repair men should stock up with some of them, for the sale promises to be large.

A Superior Automobile Jack.

The illustration shows an automobile jack that is easy to manipulate, will not get out of order, and should be in

A Reliable Auto Jack.

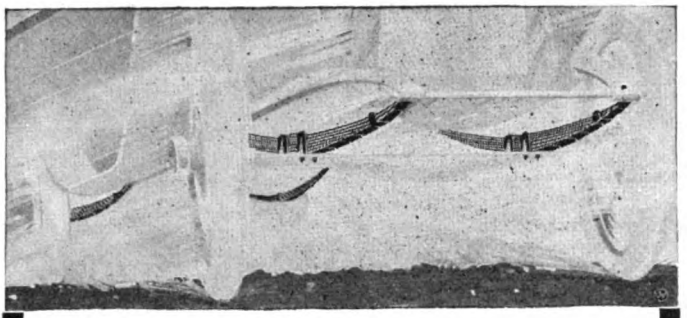


the car house of every automobile owner. It is made by I. S. Spencer's Sons, Guilford, Conn. A postal card will bring a full description of this useful device.

Spindle Connecting Bolt.

Osborne & Stephenson Mfg. Co., Plainville, Conn., make a Ford car spindle connecting bolt which promises to fill a long felt want. They promise immediate delivery in any quantity.

Automobile Battery Charging Outfits.



Hobart Bros., Troy, Ohio, have just brought out a new ½ K. W., or 500 watt battery charging appliance, which should interest the garage and allied trade. This outfit has ample capacity to enable battery charging work to be profitable to the user, and is remarkably free from at-

For battery recharging.

tention, or operating expense. Practically any one can handle this work, with no experience whatsoever. The average cost of charging a battery with this machine being approximately 15 cents and the auto owner pays from 75 cents to $1.50 for each battery charged, which means a substantial margin of profit, when seven batteries can be charged at one time. Hobart Bros. have a novel plan of selling this equipment, on a small payment each month, which guarantees the outfit giving the most satisfactory service, and means that the outfit costs practically nothing, the profits from the work usually purchasing the machine. Write for full description, price, etc.

Amazon Has New Mileage Guarantee.

A departure from the conventional tire mileage guarantee has been made by The Amazon Rubber Company at Akron, O. Instead of guaranteeing their tires for a certain number of miles, the new guarantee reads "and the mileage rendered is guaranteed to be satisfactory to the consumer." By this guarantee, if the customer feels that he has not purchased his tire mileage at the lowest possible price, he is at liberty to bring the tire back.

Profit in Painting Motor Cars.

The garage or repair shop that has not yet installed a paint shop department will find profit in so doing. Valentine & Company, 456 Fourth Ave., New York, have recently published a book entitled "The Motor Car Paint Shop Hand Book." It contains chapters on "How to Make the Paint Shop Pay," "Equipment," "Painting Methods and Materials," "Colors and Color Varnishes," "Bookkeeping and Cost Keeping," etc. This book is handsomely bound in cloth and contains just the information needed to install a paint shop department. We understand that a copy will be sent free of charge to any garage owner or repair man who may be interested in the idea of a paint department. It will be found of interest too to those who already have paint departments. We understand that the edition on this book which, by the way is illustrated, is not unlimited, so that our readers who want a copy should write for it at once.

A Superior Ford Truck Attachment.

The Unity Truck Attachment, made by the Unity Motor Truck Co., 306 Engineers' Building, Cleveland, Ohio, converts, at a low cost, the economical, dependable Ford into a sturdy, practical 1,250 lb. truck with 7 to 9 foot loading space back of seat. It is easily clamped, bolted, and securely applied to the Ford without drilling—only a wrench is needed to make a complete assembly. The firm has issued a folder which shows you at a glance why the Unity is a good, practical job. Get this folder and read about the perfect, housed main drive extension with its added universal joint, heat treated shaft and Hyatt H. D. Bearing to carry it, the 50-inch long side springs, mounted on the Ford perch and housing, the big, strong frame and long wheel base which give plenty of loading space, allow correct load distribution and avoid overhand with its consequent skidding and the two truss rods which cradle, align, and strengthen the rear axle unit.

New Wheel Company.

Promotion of a new company for the manufacture of demountable wheels is being completed in Grand Rapids, Mich. The company is to be known as the Kolben Mfg. Co., and will be capitalized at $200,000. Stock will be offered at $10 a share. The company will manufacture hubs only for wire, wood or steel wheels.

Maine Auto Road Book.

The Maine Automobile Road Book for 1917, issued annually by the Touring Bureau of the Maine Automobile Association, 12 Monument Square, Portland, Maine, is now ready for distribution and the Association feels extremely proud of its sixth annual edition. This year's book numbers nearly 500 pages and is nearly 100 pages larger than the 1916 issue which held the record up to that time. The scope of the book has been greatly enlarged and it now covers not only Maine completely, but this year it has been enlarged to include also the principal arteries of travel in all of the New England States and all of the main automobile routes in Canada from Montreal away east through Quebec to the provinces of New Brunswick and Nova Scotia. The book will carry the tourist from Washington, D. C., Philadelphia, and New York, to Halifax, N. S. Its Western limit is Albany, N. Y., its Southern limit is Washington, D. C., its northwestern limit is Montreal, P. Q., its Northern limit is Quebec and the North Shore of the St. Lawrence River, and it goes as far East as Halifax and the Land of Evangeline.

The famous Pine Tree Tour is still a feature of the book and it also includes the widely known Ideal Tour. The majority of the routes are given in both directions. The book has 25 city and town street maps, new illustrations, new and complete indexes; and features of special value are the new automobile, fish and game, and other important laws enacted by the Maine legislature which was in session this year. Other features are new maps covering every route in the book. The 1917 volume is handsomely bound in a waterproof cover and is completely filled with information of interest and of great value to the motorist touring not only in Maine, but throughout the Northwestern United States and Eastern Canada.

The 1917 Champion.

Many of the noted racing drivers having enrolled in the Aviation Corps and other branches of the service, the American Automobile Association decided to eliminate the 1917 racing championship. When Uncle Sam's imperative call takes the monarchs of the motordrome the question of racing champion must be left unsettled. There's no question as to the champion brand of lubricants. Dixon's Graphite Automobile Lubricants have won undisputed honors—hands down. In scores of races, with scarcely an exception, they have been used by the winning drivers to kill friction, for the slightest delay due to friction is fatal. That's why the winners use Dixon's and why most of the other contestants follow suit. Dixon's will serve the pleasure or commercial driver just as well as they meet the requirements of the racers. Their use means more mileage—smoother, quieter running—less upkeep cost.

New Ribbed Tread Tire.

The Mason Tire & Rubber Company has placed a new Ribbed Tread Tire on the market. This is in addition to the popular Lattice Non-skid tread which this company has manufactured since its inception. The new Ribbed Tread has a jet black top and white side wall and makes a snappy, classy appearance. In speaking of this new tire, Mr. D. M. Mason, General Manager of the Company, said: "Our new ribbed tread tire has been perfected after months of experimenting and testing. This tread has all the strength and resiliency of the well-known Mason Lattice Tread, non-skid tire and was built by us to satisfy the demand for an easy steering

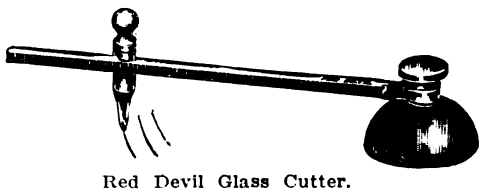
The Mason Tire.

front wheel tire to accompany our non-skid. We have designed it to make a classy appearance and it adds distinction to any car. This new Ribbed Tread, as well as our Lattice Tread, is the achievement of the best tire makers we have been able to gather together. All the knowledge of experts, who have years of successful effort behind them, have gone into these tires to make them the best we can possibly produce. In the manufacture of this Ribbed Tread we have strictly adhered to our original policy from which we have not deviated and shall not, to build a tire of the highest quality at a moderate price. The manner in which our business is growing is a source of great gratification to us. In order to fill our orders we are operating night and day and are compelled now to increase our factory facilities."

An Amazing Record.

Out in Plainville, Kansas, a month or so ago an old automobile was plugging around town in a sort of matter-of-course way. There was nothing in the steady pulse of its motor or in the old-fashioned lines of its hood to suggest that it was unique in any particular. Yet this old 1909 Buick, owned by F. E. Slason, had traveled 261,800 miles, a verified record unequaled, to our knowledge, by any other car in the world. During 1915 in the course of the Hyatt record mileage contest, this car was brought from its undeserved obscurity into national renown. Because every mile of its thousands has been covered on its original set of Hyatt Quiet Bearings, the old Buick is now known as the "Hyatt Roller." The Hyatt Quiet Bearings in the car are at the differential, on the pinion shaft, and in the rear wheel hubs, where they get the greatest grind and wear; they would naturally be expected to be the first parts to give way. But they haven't. They are still there, requiring only occasional lubrication and never needing adjustment or other care. But the old car has recently swelled its astounding mileage record by twelve thousand miles, additional and absolute proof of the wonderful durability of Hyatt quiet bearings.

Cylinder Grinding.



Butler Mfg. Co., of Indianapolis, who specialize in cylinder regrinding, pistons, rings and pins, have not raised their prices despite the fact raw materials have undergone a decided advance. This is an enviable record and they are doing all in their power to retain it. The factory is operated on a production basis; the very best and latest machinery is used and high efficiency is maintained. Devoting, as they do, their energy to this one line, the management is enabled to make a careful study of the work. Wages have been increased to keep pace with the high cost of living, and the spirit of loyalty is strong among the employees. Honest, intelligent service is always the aim of the company, and among machinery houses they have a reputation of requiring more accurate machinery for all of their work than the majority of manufacturing plants.

Safety for Tires and Wheels.

An equipment that will prevent wheels from breaking over and punctured tires, is being sold by the Stone-Thompson Mfg. Co., 1502 Michigan Ave., Chicago, Ill. It also makes demountable wheels of the wheels now on Ford cars. Little labor is needed to apply them, and the equipment can be installed in a few minutes. There will, no doubt, be an extremely large sale for the Stone Demountable Wheel as soon as it becomes fully known, and we advise dealers to make application for the agency of this outfit at once. It makes a quick, demountable wheel of the wheel now on the Ford car, while the regular tire equipment is used. The cost is low and the firm is now ready to receive orders.

Circular Glass Cutter.

The latest addition to the extensive line of "Red Devil" tools is reproduced herewith. This is a "Red Devil" Circular Glass Cutter and embodies some notable improvements over the old tool of this kind. This is designated as style No. 263 and is a convenient tool for cutting automobile headlights, either from plain or sheet glass, from 2 to 22 inches in diameter. It consists of a

Red Devil Glass Cutter.

metal base with a rubber mat to prevent it from slipping. It is also provided with a nickel-plated steel rod, graduated into 16ths of an inch, for adjusting the size of headlight glass required. The cutting head, which contains the cutting wheel, has an adjustable set-screw. It is most useful for automobile owners, dealers and garage men who prefer to cut their own headlights rather than keep a large stock of them. The manufacturers are Smith & Hemenway Co., Inc., 83 Coit St., Irvington, N. J.

New "Cork Insert" Ford Fan Belt.

The Advance Automobile Accessories Corporation of Chicago, announces a new Ford fan belt. This belt is based on the same idea as underlies "Cork Insert" Transmission Linings for Fords. Circular pieces of cork are inserted into high grade tanned and stretched strips of specially waterproofed oak leather. The corks are backed up by heavy fabric and cannot become loose or slip out. The effect of this fan belt is to eliminate the slipping which cuts down the efficiency of the ordinary belt. The fan belt is subjected to very hard service. It is exposed to water, oil and grease. Grit and dirt are ground into its surface. The normal effect of service likewise, is to wear it smooth and polished from the

Ford Fan Belt Improvement.

constant friction. All of this tends to destroy its gripping properties until the element of slip becomes great. Cork Insert Fan Belts reclaim this lost motion. They make the fan turn with the motor, and eliminate the slip, because the corks are not affected by water or oil or grease or dirt. Cork retains its gripping qualities indefinitely and wears slowly, so that its use results in a fan belt not only of increased efficiency, but of greatly prolonged life. Cork Insert Fan Belts for the 1917 model of the Ford retail for $1 and for other models, 85 cents.

Bodies for Ford Cars.

The Parry Mfg. Company, Indianapolis, Ind., have issued an attractive catalogue showing an unusually comprehensive line of bodies for Ford car chassis. These bodies are guaranteed to stand up under the hardest kind of usage. They ought to sell unusually well and dealers will take very little risk indeed, if they investigate this matter and stock up with a line of them. Catalogues will be sent giving full description.

New York Office for Osgood.

The Osgood Lens Supply Company, of 2007 Michigan Ave., Chicago, Ill., have opened a New York office at 1834 Broadway, New York City. This office will be in charge of G. E. La Vietes, who is already well known in the trade. No doubt the business of the Osgood Lens & Supply Co. will thrive in the New York territory under the able supervision of Mr. La Vietes.

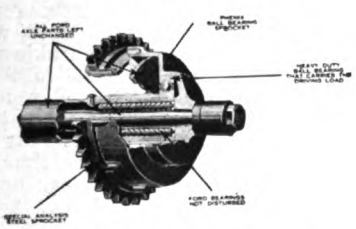
Price—$350.00 F.O.B. Chicago.

1½ Ton Capacity $350

Phenix TRUCK 3000 LBS. CAPACITY MAKER $350



Carries 90% of the Load—Prevents Broken Rear Axles

The Ford power plant is built to carry the ordinary equipment and body of the Ford passenger car, plus five passengers, at most. Its surplus strength is sufficient to care for ordinary overload. It does the work for which it is built.

But the Ford power plant will *pull* many times the weight it will carry—and on this basis the PHENIX Truck Maker is built.

There is no danger of overloading the power plant of the PHENIX Truck Maker, or of putting undue strain on the motor. At no time is the motor or car—even when hauling the maximum load—subjected to greater strain than when traveling at moderate speed as a pleasure car. The PHENIX Truck Maker—with its massive construction and broad, heavy, artillery type wheels, *carries 90% of the load,* safely and easily. *The Ford part of the unit merely pulls it.*

And, besides, ball bearings in the bell housings of PHENIX relieve Ford axles of strain and prevent breakage. Extra heavy springs carry the load with ease, and the efficient brakes operate metal against metal.

Special Ball Bearing Sprocket Prevents Rear Axle Trouble

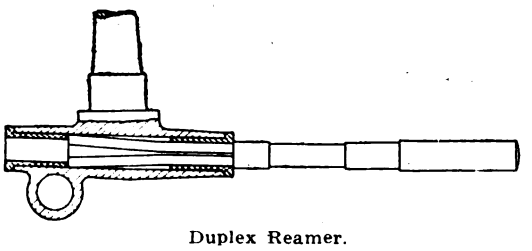
BROTHER—Accidentally discovered root, cures tobacco habit and indigestion. Gladly send particulars. G. A. Stokes, Mohawk, Fla.

A New Ford Car Tractor.



The E. G. Staude Manufacturing Co., St. Paul, Minn., make a tractor for Ford cars, which allows plowing in the morning with the car, and taking it out for pleasure in the evening. It is said to be superior to a three-horse team for plowing, and it will pull a 7-foot double action disc easily. The firm is having a big sale for these tractor attachments and all because it gives universal satisfaction.

Safety Brakes.

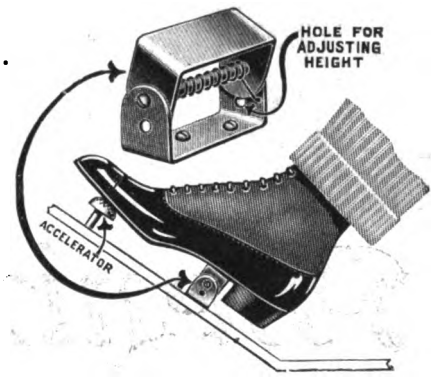
The Never Break Products Co., Bangor, Pa., make an adjustable brake for Ford cars that will fit any model. The brakes for rear wheels cost only two dollars, and they are guaranteed without conditions. No changes to make to install them, and by their use absolute safety is secured.

A Useful Tool.

The G. H. Dyer Co., 155 Brookline St., Cambridge, Mass., make a Duplex Reamer for Ford cars, which does the work quickly and accurately. It is illustrated herewith. They make other indispensable tools for Ford car work, and they are all moderate in price, and highly useful in the garage.

Duplex Reamer.

A Reliable Ford Car Lock.



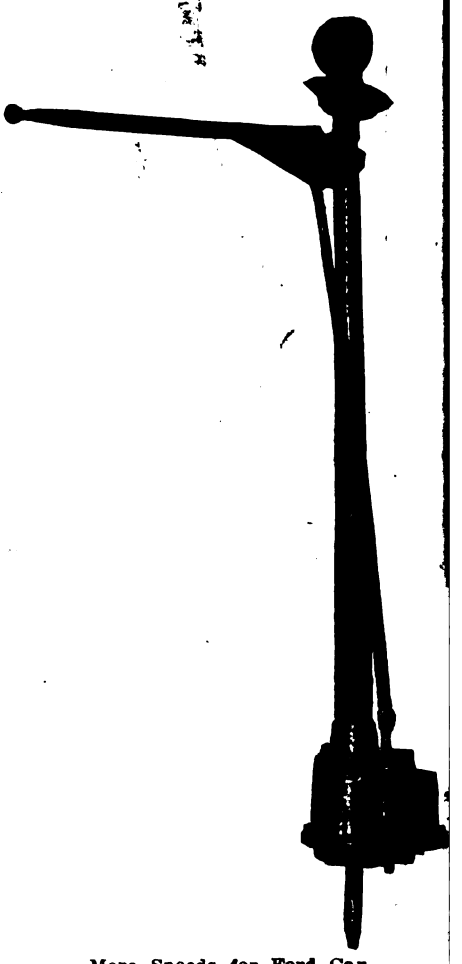
The Syracuse Universal Mfg. Co., Inc., Syracuse, N. Y., make a lock for Ford cars that they sell for $1.50. It cannot be picked and has 1,000 combinations. It is installed in three minutes, and is being distributed by 165 jobbers in this country and Canada. Dealers are advised to write for discounts.

Main Battery Charging Set.

The Main Electric Company, Pittsburgh, Pa., is marketing a battery charging outfit, which is substantial, reliable and is positively guaranteed. No city current is necessary—it generates its own electricity. Operates from a line shaft or engine by belt drive. Charges from one to five lighting or starting batteries at a time. Any voltage, 6 volts up to 30. Large profits are made by charging batteries from this outfit, practically all clear profit. Usually driven from power previously installed and in operation, making no additional operating expense. Makes you independent of a lighting circuit and doubles your profits. Simple to install, no necessary upkeep. Immediate deliveries. Bulletin No. 42 on request.

Relieves the Driver.

The New York Coil Company, 338 Pearl Street, New York, have just placed upon the market a device intended to relieve the foot and leg of all strain and prevent the irregular application of power to the engine, which is so noticeable in driving over rough roads or "bumpy" streets. The device consists of two members formed of drawn steel with a rod running through both pieces so that the top member rocks backward or forward at the same time carrying the entire weight of the leg and foot, which allows a gradual application of power and enables the operator to keep the accelerator fixed at any position desired The spiral spring keeps the upper member in an upright position and means are also provided to raise or lower the device to suit any height of accelerator. The supporter is heavily nickel plated, and sells for seventy-five cents.



Easy acceleration.

An Emergency Axle.

Ekern Bros. Mfg. Co., Flandreau, South Dakota, make an emergency axle for Ford cars, which is quickly installed. weighs but 8 pounds, costs little, and when needed is likely to be needed very badly indeed. It ought to be an attractive device for Ford car owners.

Woodford Auxiliary Transmission.

With the increasing use of Ford truck attachments, the necessity for a more flexible range of gearings than that which can be had from the standard Ford construction which gives but two gear ratios, has become very apparent. A construction built for this special purpose has been invented in Los Angeles some time ago, and has been manufactured and marketed successfully for more than a year. This construction is an auxiliary transmission giving two speeds, and when used in conjunction with the Ford transmission four gear ratios are available. The transmission is of the sliding gear type, enclosed in a gear case seven inches long. The drive shaft and torque tube is cut, shortened to the proper length to allow for the transmission and the tube seams rewelded. The transmission is then bolted on to the drive shaft and is ready for installation. The makers claim that in addition to the obvious merits, it has another which is extremely desirable to Ford owners either for pleasure cars or truck purposes. The transmission provides a positive neutral point, no gears engaged. This is distinctly a great safety factor, and likewise permits the car to be pushed around without any transmission drag or braking effect. The transmission is bolted to the rear end of the drive shaft, and a flange ready drilled is provided on the transmission case for bolting to the rear axle. Any mechanic can make the change in about one hour on a Ford car or about two hours on a truck type. $52.50 is the price for the complete assembly, and a credit of $7.50 is allowed for the return of the old drive-shaft and torque tube. This makes the net retail price $45.00 F. O. B. Los Angeles. This device is manufactured by the Woodward Truck Attachment Company, 2035 W. Pico Street, Los Angeles.

More Speeds for Ford Car.

AUTO THIEVES NOW FOILED!!

WALKER KE-LES AUTO LOCK

No Key to Lose
No Keyhole to Find

For All Cars— Gasoline Electric and Steam

Dealers! Here's THE Auto Lock!

Cuts Off Gas, Battery, Magneto, Self-Starter

You can see at a glance, Mr. Dealer, that the Walker Ke-Les is the *right* idea in an auto lock. No key of any kind is used. The Walker Ke-Les works on the combination principle. Same principle as the combination lock for modern burglar-proof safes and bank vaults—only much simpler. Over 3,500 Walker Ke-Les Locks already in use. It is the lock that motordom has always wanted. It is the lock that the dealer has always wanted to sell. It is the one lock that makes every car—gas, electric and steam—absolutely safe from theft.

$10 ($15 Properly Installed)

100% Profit

80% of the business you do yields you a profit of only 15 to 30%. On the Walker Ke-Les Auto Lock you make a profit of 100%. You sell the lock for $10 and get an extra $5 for installing it. We advertise this $5 installation price broadcast so that you are protected on it.

Immediate Delivery

No matter what your experience has been with other so-called "Auto Locks" you'll find the Walker Ke-Les to be the one right proposition in every respect, from the merit of the lock itself to the matter of keeping dealers always supplied.

WRITE! Mail the coupon and get Descriptive Folder on this marvelous auto lock; our dealer's proposition; particulars of our money-back guarantee and our big, national advertising campaign.

WALKER KE-LES LOCK CO. JAMES H. CUMMING, Sales Manager CHICAGO, ILL.

SPECIAL FEATURES

No key to lose or leave in lock. No keyhole to find.
Over 87,000 changes to the combination.
Locks and unlocks faster than one could find his key.
No complicated mechanism or tumblers—just smoothly operating discs. Can't get out of order.
Can be installed on any car—gas, electric or steam. Sets flush with dash or instrument board, right in front of driver.
Absolutely prevents "back-fire" from setting car afire.
Complies with Insurance, Fire and Police requirements regarding cars standing in street.

The TRUCKMOBILE and YOU—

The truck attachment idea is admittedly the sensation of the automobile industry. Its growth in the few short years of its existence has been without equal. Dealers, who only a few months ago scoffed at the idea of presenting a truck attachment, today are selling hundreds of them.

This is your opportunity to do the same. But in selecting a truck attachment dealership you want, above all, to represent the one that is biggest in actual construction, biggest in correctness of design and engineering, biggest in performance, biggest in consumer value, biggest in dealer profit—in every way

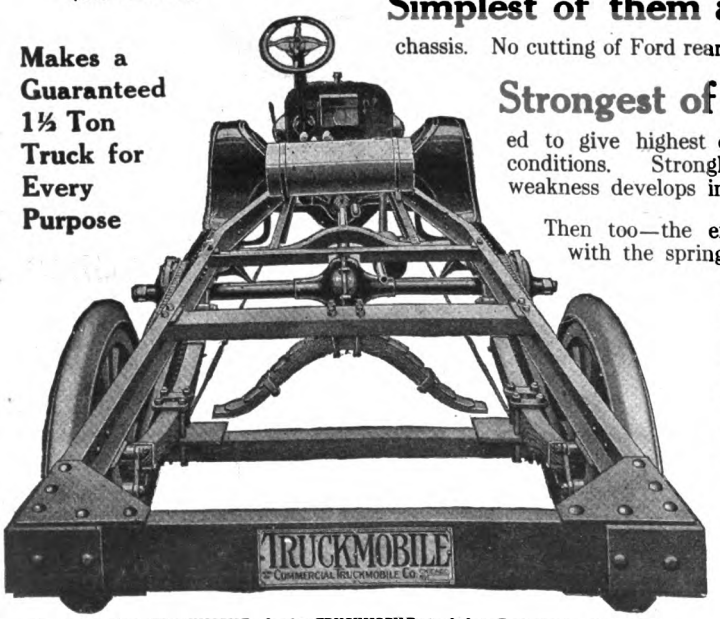
"Biggest of them all!"

From among the many big points of superiority of the TRUCKMOBILE we list these four—unique to the TRUCKMOBILE—which make it stand out above all others:

$350

And a Ford Chassis
(Old or New)

Makes a Guaranteed 1½ Ton Truck for Every Purpose



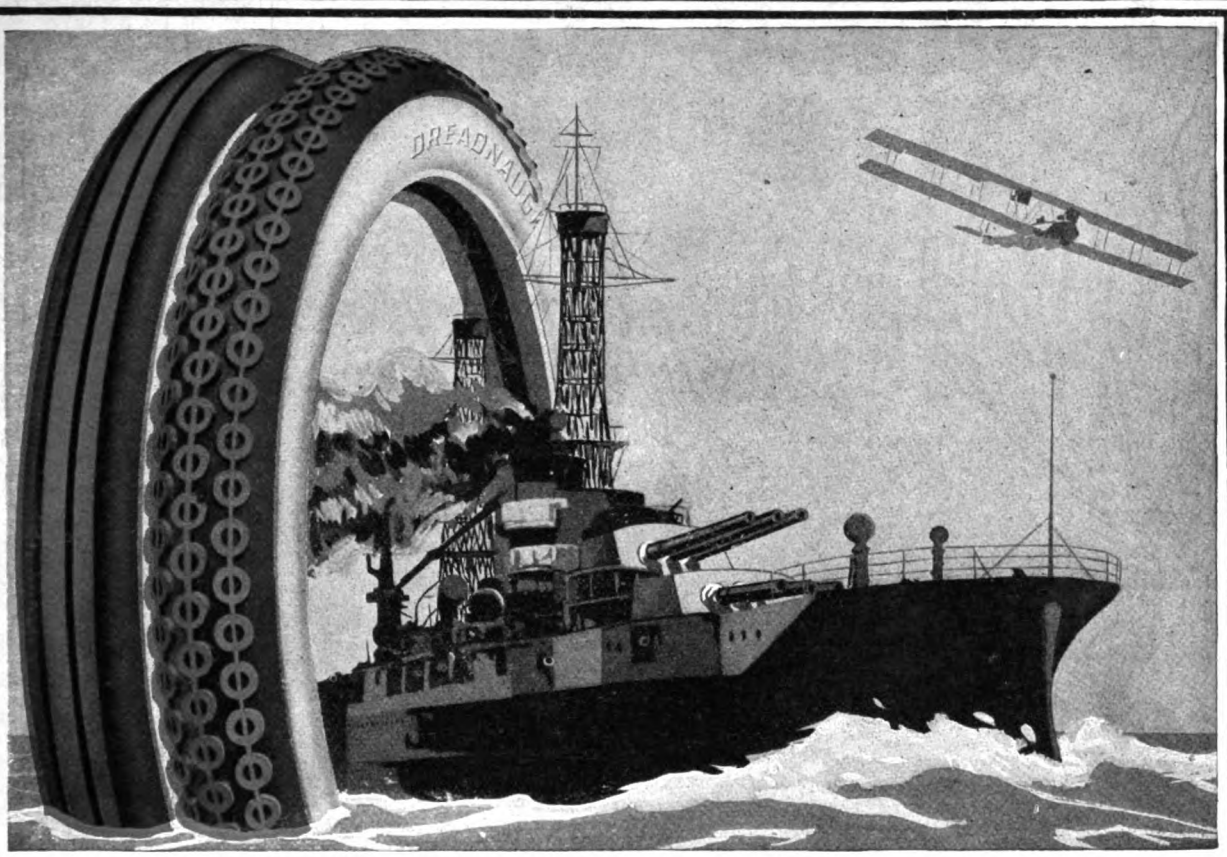
Widest of them all— 6 to 9 inches wider frame than any other gives added stability and sturdiness and eliminates the sidesway with its drag on the motor and wear on bearings.

Longest of them all— 133 inch wheelbase permits greater loading capacity and makes it easiest riding and easiest steering of them all.

Simplest of them all— Fewer parts and less of dealer's time spent in attaching to Ford chassis. No cutting of Ford rear axle or housing necessary.

Strongest of them all— Massively, though simply, constructed to give highest degree of service under any and all conditions. Strongly reinforced at every point where weakness develops in others.

Then too—the exclusive method of spring suspension with the springs interposed between frame and axle, the quickly attached bell sprocket. Add to this the fact that the TRUCKMOBILE is the greatest value for the money—most economical of them all in tire and gasoline mileage, cost of operation and upkeep. All these things make it **Best for the Dealer to sell because it is Best for the User to buy.** Write today for attractive dealer's proposition.



Rear view of the TRUCKMOBILE, showing TRUCKMOBILE attached to Ford chassis. Note massive construction, heavy reinforcement of frame and position of spring interposed between frame and axle.

Commercial Truckmobile Co.
400 Truckmobile Bldg.
Chicago, Ill.

Biggest of them all!

DREADNAUGHT TIRES

To Dealers: DREADNAUGHT TIRES are the most rugged, durable, smoothest riding and best withstand the ruthless grind of the road. The handsome Red Treads combined with the soft-toned ivory side-walls add smartness and distinction to the car.

THE DREADNAUGHT instantly has won the favor of the public wherever introduced.

5000 MILES GUARANTEED

DREADNAUGHT Red Silent "Vacuum" Tread is a positive anti-skid. The bar through the centre of cups prevents clogging and minimizes noise and road friction.

DREADNAUGHT Red "Ribbed" Tread replaces to great advantage the old-fashioned plain tread.

THE NAME IS AN ASSET TO THE DEALER

Liberal supply of interesting literature and the most attractive advertising devices ever issued by a tire company sent to all of our representatives.

We have an exceptional proposition and assure excellent service with intensive co-operation from our organization. Write or wire, Department "Y"

Beautifully illustrated booklet, "*The Evolution of the Battleship*," by Henry McDonald Spencer, sent free on request.

Screen Block
This screen block fits between carburetor and intake manifold and contains air spray nozzle for supplying air to mixture and a fine wire cloth mechanically break mixture into finer form.

Construction
Hoosier Sub-Carburetor, made of the finest materials: aluminum, cold rolled steel, cast iron. Fully guaranteed for life of motor on which it is installed.

Automatically Regulated
Control of volume of air passing into the mixture automatically regulated by throttle control. You get an exact mechanical mixture, just right for highest efficiency at all engine speeds.

Valve
Controls volume of heated air passing into the mixture, giving exact proportions necessary for all conditions of motor operation.

OVER 4,000 Hoosier Sub-Carburetors have already been sold—over 3,000 enthusiastic testimonials have come in to us entirely unsolicited. Everyone says: "Hoosier Sub-Carburetor is the greatest economy device ever put on to a motor."

Heated air is drawn from the logical place — around the exhaust pipe. It is injected into the mixture at the proper point just after the mixture leaves the carburetor. The amount of air is mechanically regulated. You get a rich mixture when you need it—starting or running on low engine speeds. You get a more economical, more explosive mixture when you want it—at high engine speeds. That is why users of Hoosier Sub-Carburetor say: "If we had to pay five times as much for it, we would gladly do so because of the results it gives."

Any Good Garage Man will Verify This

How does Hoosier Sub-Carburetor increase mileage? It breaks the mixture up into finer form—gives it more air.

NOTE—About 87% of the gasoline taken into a motor with an ordinary carburetor comes out from the exhaust unexploded. It is not sufficiently vaporized. Hoosier Sub-Carburetor cuts down this waste by a big percentage by breaking up the mixture and vaporizing it much more completely.

How will Hoosier Sub-Carburetor prevent carbon? Carbon is formed from unexploded gasoline in contact with lubricating oil.

Hoosier Sub-Carburetor greatly reduces the amount of unexploded gasoline. Prove this by opening the pet cock on a motor not equipped with Hoosier Sub-Carburetor. You get a dull red blaze without Hoosier Sub-Carburetor. With it you get a clear, steel-blue blaze.

How does Hoosier Sub-Carburetor give more power and speed? It breaks up and vaporizes the mixture — makes it more combustible — gives a quicker and more powerful explosion.

How does Hoosier Sub-Carburetor give greater flexibility? Motor flexibility comes from the proper regulation of a mixture and a more rapid explosion. When the gas explodes rapidly, the motor does not load up.

We Guarantee These Results

We positively guarantee, with a 30-day money-back clause, the amazing results obtained by Hoosier Sub-Carburetor users.

40% greater mileage. 35% greater power. 30% more speed. Wonderful flexibility—easier starting—less carbon.

Use Hoosier Sub-Carburetor on your own car. If you don't get these results send it back; we will gladly refund your entire purchase price within 30 days of your purchase.

Amazingly Simple to Install

You can install Hoosier Sub-Carburetor in a very few minutes — do all the work yourself if you want to. Full instructions accompany each device. After you have once put it on your motor, you will hardly recognize your car as the same one you were using before you made the installation. It will put the "pep" of a new car into any old motor. It will make any new motor tremendously more efficient.

3176 testimonial letters from 4000 users — UNSOLICITED

Wanted—Exclusive Dealers

The Hoosier Sub-Carburetor will sell like wildfire to every car owner. As soon as you get your contract we will prove results on cars in your territory—ready for you to start sales. We will back you with big national and local advertising. Prove to us that you are the best equipped and responsible. Write, wire, phone or jump the first train for Indianapolis; get this fastest selling accessory; a money-saver for any car owner—a money-maker for you.

Better Than 30 Miles

I put the Hoosier Sub-Carburetor on my car and filled the tank full, and when the gauge showed three gallons, my speedometer read 214 8/10 miles, which is a little better than 30½ miles to the gallon. I was averaging 100 miles to five gallons of gasoline before I installed it.
D. L. STINSON, Twin Buttes, Ariz.

Speed—Power—Less Carbon

I am well pleased with my trial. I get more speed, power, less carbon, and the engine runs a great deal smoother.
J. A. TEAGARDEN, Auburn, Cal.

Could Not Be Without It

I installed the Hoosier Sub-Carburetor on my car a few days since and made a trip of 20 miles through heavy mud roads. I closed my needle valve nearly one-half turn and the engine had more power and pep than it ever had before. In fact, I could not get along without it.
C. L. HOOKER, Crowley, La.

Average 24½ Miles

Your favor of the 28th received. During 10 days' use of the car it covered 514 miles on 21 gallons of gasoline or an average of barely 24½ miles to the gallon.
WM. A. HOWE, Pasadena, Cal.

Big Gain Over All Others

My tests were as follows: Miles per gallon of gasoline on Ford car, with no other changes except carburetors. With Kingston Carburetor, 18 miles per gallon; Holly Carburetor, 22 miles per gallon; Stromberg Special Carburetor, 27 miles per gallon; Hoosier Sub-Carburetor, 31½ miles per gallon.
R. E. BEERS, Pond, Cal.

Runs Like a New Car

My car is 2 years old in November and with your Carburetor it runs like a new car.
C. E. EDWARDS, Buhl, Idaho

SUB HOOSIER CARBURETOR

Ready Now
Ship Anywhere
Get it

YOU are a live dealer—wide awake to real selling propositions. It won't take you a minute to see why this wonderful device is certain to be your biggest seller.

Thousands of devices have purported to give economy, flexibility, speed, power. Where are they now? They are not on the market. What is the reason? Simply the fact that they did not make good when they were used by car owners. If they had made good they would still be selling like wildfire. Gasoline price is going up. Car owners must get more mileage.

Hoosier Sub-Carburetor is a proved economizer—a proved power and speed developer—a proved advantage to any motor. It has made good.

You have already seen big evidence of this fact. Over 4,000 Hoosier Sub-Carburetors have already been sold—over 3,000 enthusiastic testimonials have come in to us entirely unsolicited.

These 4,000 users came without any sales effort at all. No advertising. No big dealer campaign. They were orders that came just because car owners wanted Hoosier Sub-Carburetors. But they are of tremendous value to you. They show you that Hoosier Sub-Carburetor is a real selling proposition.

This is Your Big Chance

Hoosier Sub-Carburetor is going to be the fastest selling accessory ever offered dealers. All the preliminary work has been done. The tests have been made—owner satisfaction has been proved. Our advertising campaign will be tremendous, in all the big national publications. We are going to sell Hoosier Sub-Carburetors for you.

Big Mileage Increase

I went 176 miles without the Sub-Carburetor. Left with a full tank of gasoline, when I got home I had one inch left in the tank. Then the next Sunday I went 194 miles. Left with a full tank of gosoline and when I got home I had 3½ inches left in the tank.
H. BEHUKEN,
San Francisco, Cal.

40% Increase

On my trip to Washington, D. C., and return, my average mileage was about 16 miles per gallon, with my Inter-State Six. Before installing the Hoosier I did well to make 11 miles per gallon. The increased power is certainly noticeable. It's a dandy.
DR. J. M. SINGER,
Dunkirk, Ind.

9 Miles Increase

Mileage has been increased from twenty to twenty-nine miles on each gallon of gasoline used.
HARRY O. WILSON,
National Military Home, Ind.

Gained Over 15 Miles

Got 34 3/10 miles per gallon of gasoline, where without it I made only 18 5/10 miles over the same road and in the same time under the same conditions.
A. McALEXANDER, San Diego, Cal.

Very Good

We gave your Sub-Carburetor a good test and made 19.4 miles without and 26.2 miles with it. I think this is very good.
HERZOG'S FURN. CO., Saginaw, Mich.

Doubled Mileage

I have purchased a Hoosier from you and have it on my car, getting from 25 to 35 miles on a gallon of gasoline, where I didn't get but 12 to 18 before I put on the Hoosier.
B. E. HARRIS,
Americus, Ga.

More Snap and Vim

I had been getting from eighteen to twenty miles on a gallon of gasoline, but with your Sub-Carburetor I got an average of thirty-two miles and more snap and vim to motor.
DR. H. K. RADCLIFF,
Dunkirk, Ind.

The demand in your territory will be instantaneous.

Bigger than any demand you have previously experienced for any accessory.

What automobile owners have tried to get in other economizers, they do get in the Hoosier Sub-Carburetor. The time was never so ripe as it is now for a real, practical gasoline saver—power and speed increaser—than can be used on any make of car.

The possibilities are stupendous. Your time for action is limited.

Dealers are already being closed up in tremendous numbers in all parts of the country. If you are a distributor you can make Hoosier Sub-Carburetor the biggest producer you have to sell. The demand will be so tremendous—so spontaneous that all you will have to do is to take orders.

Practically every user of a Hoosier Sub-Carburetor has sold several more to his friends. Take advantage of this tremendous wave of business.

Don't Forget The Money Back Guarantee

If we had not already shown you the tremendous number of unsolicited testimonials that have come to us, our "Money Back in Thirty Days" guarantee would be sufficient evidence that we have an accessory of proved value. For we put the proof entirely up to the user.

A few minutes' work and the Hoosier Sub-Carburetor is installed. Then the user has thirty days to prove its wonderful advantages.

Whatever else you do, wire now for this big seller.

You Want This Real Economizer On Your Car

We don't have to prove to you that you need this wonderful economizer. Over 3,000 automobile users have already proved it by their own experience.

We don't have to argue about the wonderful merits of Hoosier Sub-Carburetor. Our wonderful money-back guarantee is your protection. If within thirty days after you use it you feel that you can do without it, return it to us and get your money back. The only thing we want to say to you is, "Get your order in early. Send the Coupon. You have thirty days in which to satisfy yourself of the results.

An electric hand crank you can sell *to* Ford owners

Ford Owners are looking for a starter that fits the Ford

In cars other than the Ford, the electric starter is *built-in*. Not only is the starter designed to fit the car, but the car is designed to fit the starter. But in a Ford, this is different. When you install an inside-the-hood starter, you interfere with the essentials of Ford design.

But the Eveready Ford Starter is literally an electric hand crank. It sits outside the hood on the cross channel member of the chassis, right where the crank grows, and it does its job just exactly as the crank does it—not by a one-direction pull, but with a complete rotary twist. Its weight is off the engine base. It does not disturb the balance of the motor nor the distribution of weight on its three suspension points. It cannot cause undue wear on the main bearings. It does not fill up the cooling air space under the hood. It is free from the side-thrust, the noise, and the nuisance of chains and gears. And when you have engine repairs to make, it is no more in your way than your lamps or springs. This is the starter you can sell.

There is still some uncovered territory on our distribution map. The Eveready Starter presents a wonderful opportunity to live dealers. Mail coupon below for particulars.

EKERN'S EMERGENCY AXLE No. 3 FOR FORD CARS.

With this device you can place the Ford Car on its own wheels in two minutes. Knock the broken axle stub out of the wheel hub, place wheel on Emergency Axle Stub and hook the Device on the flange of the Axle Housing and the Ford can be pulled in at any speed desired with safety. Weight 8 lbs.

Sent Express Prepaid to any address in the United States for $4.90. Cash with order.

EKERN BROS. MFG. CO., Flandreau, SOUTH DAKOTA

Useful for Car Owners.

The Aerofram Company, Inc., 105 Massachusetts Avenue, Boston, Mass., make a union connector for dry cells which is highly recommended. Their

Aerofram Gasoline Saver only costs a dollar, and can be attached to any car in ten minutes. It increases power, keeps down carbon, and makes the motor run better in every way.

New Specialty Devices.

The Star Specialty Manufacturing Co., 227 West Erie Street, Chicago, Ill., have issued a series of circulars describing and illustrating their products. Among the most important of these products is a small starter for Ford cars that costs little and a gasoline-tight piston ring. There are a good many others in the list, and accessory dealers should write and get all of these folders, which describe articles that ought to sell well.

America First.

During these trying times it is not only incumbent upon us all to be patriotic, but to let others know that we are for America first, and at all times. The

flag illustrated herewith for automobile hoods is an unusually attractive one. It is being made by The Art Metal Works Co., Inc., 7-15 Mulberry Street, Newark, N. J., and its cost is nominal.

Announcing The

A Personal Talk with Dealers

Are you ambitious to hit the business grade at higher speed? The coming year promises a whopping big demand for high grade cars. How much of that demand will you supply in your territory? It depends upon the car, not which you represent, but which represents you.

Every car has features which appeal to some people. The perfect car would be one appealing to everybody. That car hasn't been built yet. The next best car, the one that will accelerate your business for you, is the one which appeals to *most* people. The balanced car.

You say—"Sure! That's the car I want. Where is it?" We can say that

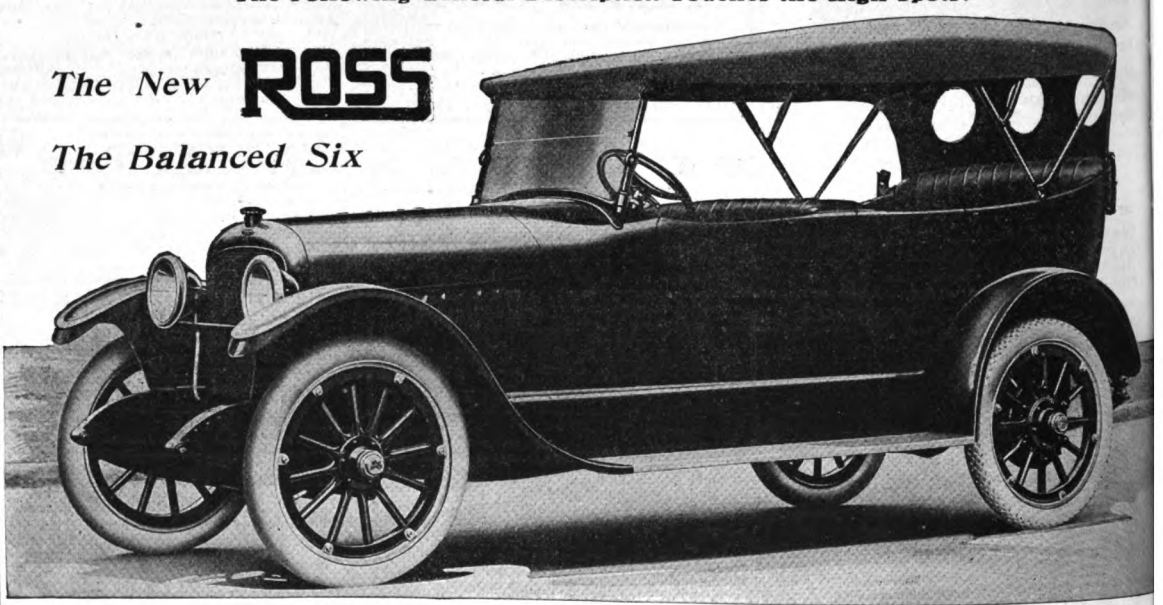
The New Ross Six is the Balanced Car

Saying so doesn't make it so, but behind the Ross are the factors that do make it so. What are they? *Knowledge of what the Public wants and the experience to produce it.*

The Ross Six is successor to the tried and proven Ross Eight, which performed stunts unequalled by any car of similar price. (Details upon request.) Another superior feature of special import at this time is added to the Ross characteristics—Fuel Economy.

The Ross Automobile Company is now under new management—aggressive men of broad experience in the automobile industry who will put the New Ross in the front rank and take some good live dealers with them.

In selecting dealers, numbers are not the object. It is more important that representatives are keen, progressive men, who can be relied upon to carry out the broad ideals of service planned for the Ross.



Dealers will be selected carefully, and correspondence is desired with responsible men who are looking for a car of unusual sales possibilities.

A Balanced Car—A Balanced Sales Plan—A Balanced Distribution

The Following General Description Touches the High Spots:

The New **ROSS**

The Balanced Six

General Specifications:

Bodies: 7 Passenger, 4 Passenger Suburban Type, 3 Passenger Roadster, Coupe, Sedan and Town Car.
Design: Full streamline, one man top. Unusually refined in design and finish
Upholstering: Rich, blue mottled Spanish leather.
Windshield: Rain-vision; ventilating.
Motor: Continental 6-cylinder. (See opposite page.)
Transmission: Selective sliding gears; 3 speeds forward and reverse; chrome nickel-steel gears and shafts.
Clutch: Multiple disc.
Axles: Full-floating rear; front I beam section.
Starting and Lighting: Two-unit system.
Lubrication: Force feed, pump driven to cylinders.
Radiator: Cellular type. Ample capacity.
Control: Center.
Steering: Irreversible, left hand drive.
Steering Wheel: Eighteen inches, corrugated, tilting type.
Drive: Shaft drive; universal joints.
Springs: Semi-elliptic front (42x2 inches); semi-elliptic rear (57⅞x2½ inches).
Wheel Base: 130 inches.
Wheels: Extra selected second-growth hickory. (Wire wheels furnished at additional charge).
Tires: 35x4½ inch Non-skid, rear; plain front.
Rims: Quick Demountable.
Horn: Motor Driven.
Instruments on Cowl: Speedometer, ammeter, ignition switches, oil pressure gauge, cigar lighter, electric lights, with 10-foot extension cord always ready with automatic take-up.
Equipment: Tire repair kit, jack, pump, tire carrier, 1 extra rim, tools, etc.
Weight: (7 passenger) 3250 pounds.

Price, $1750 For 7 Passenger, Suburban type and Roadster

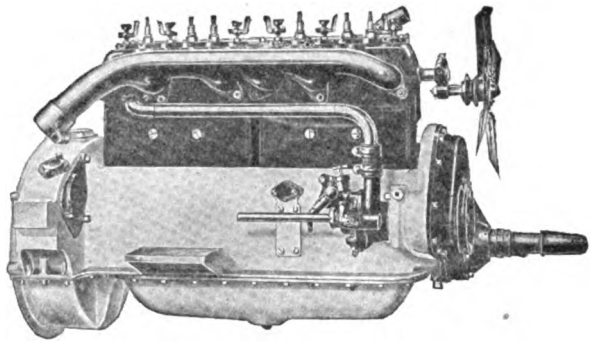
New Improved ROSS
The Balanced Six

What Car Balance Means

The motor is the brain of a car. Like the brain of a man it manifests its energy thru the body. Every part of the body must work in perfect harmony with the brain or much of the energy is wasted. Perfect balance in man or car is essential to most effective action.

The Brain of the Ross Car

First of all, for perfect balance, the brain must be efficient. In selecting a brain for the New Ross, experience said—"Continental."



Investigations, comparisons and rigid tests proved the Continental to be the dependable and powerful brain the Ross ideals demanded.

Experienced automobile men will agree that the Continental is "there with the goods." A six cylinder type was selected because "sixes" are most popular, the Public having learned from experience that six cylinders are necessary for proper flexibility and power, and that the few advantages to be gained by more than six do not compensate for the added cost of fuel and maintenance.

How Balance Is Obtained

Having the proper brain or source of energy the rest of the car must be so designed and connected with it that every ounce of power can be utilized, controlled and made the ready servant of the man at the wheel. The Ross designers are past masters of this kind of designing.

To attune every part of the car to perfect harmony with the motor, to develop a marvel of control, to gain unusual speed of acceleration without sacrifice of other qualities, to turn out a balanced car, that was their job. How well they succeeded is evidenced by the amount of new business and the keen interest and enthusiasm manifested by both dealers and consumers.

Continental Red Seal 3 1/2x5 1/4 Motor

The Continental needs no other recommendation to experienced automobile men than its reputation established by performance.

The Continental is the product of the largest exclusive motor manufacturers in the world. Specialization and efficiency of enormous production are responsible for Continental supremacy. A supreme motor for a supreme car.

A Balanced Sales Plan

The Ross ideals of car performance have resulted in feats such as going up Lookout Mountain locked in high, carrying seven passengers weighing 1103 pounds, at an average speed of 27 miles per hour, a feat never before accomplished by any car; taking the celebrated Fillmore Hill in San Francisco, the terror of motorists, locked in high, with apparent ease, and many other rigorous tests of power and flexibility.

These ideals have been applied to the selling plan as well. The brains behind it must be the best. The Ross must take the market on high also. Sales co-operation, advertising, dealers' business promotion, every factor of the selling organization is balanced.

The best merchandising talent possible have laid the plans for real aggressive sales conquests.

Dealers who are selected to handle the Ross will find themselves part of a well balanced organization, pulling together with one object—to make the Ross the most popular car on the market.

Business Prospects Now Best This Country Has Ever Known

Unsettled conditions this Spring have retarded sales. But since the tension due to the money market has been materially relieved, the automobile industry is on the verge of the greatest production era in its history. This is shown by the inrush of orders to every factory. The characteristics incorporated in the Ross cars appeal especially to these prospective buyers and the wide awake dealer who "gets on the job" now, will not only get the best picking from this season's market, but will establish a firm foundation for a wonderful future business.

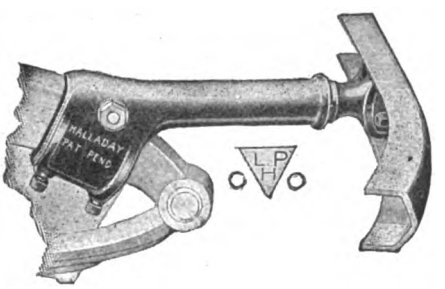
The Brilliant Constellation of the HALLADAY LINE.

No Matter What Car You Sell or Use



In the HALLADAY LINE

There is a Bumper to Fit it—Front and Rear

Accessory dealers who carry this line are in position to control the Bumper Business in their territory.

Halladay Quality is known thruout the trade as highest attainable and

Halladay Design is invariably up to the minute and always ahead of the others.

Here is an example of the new

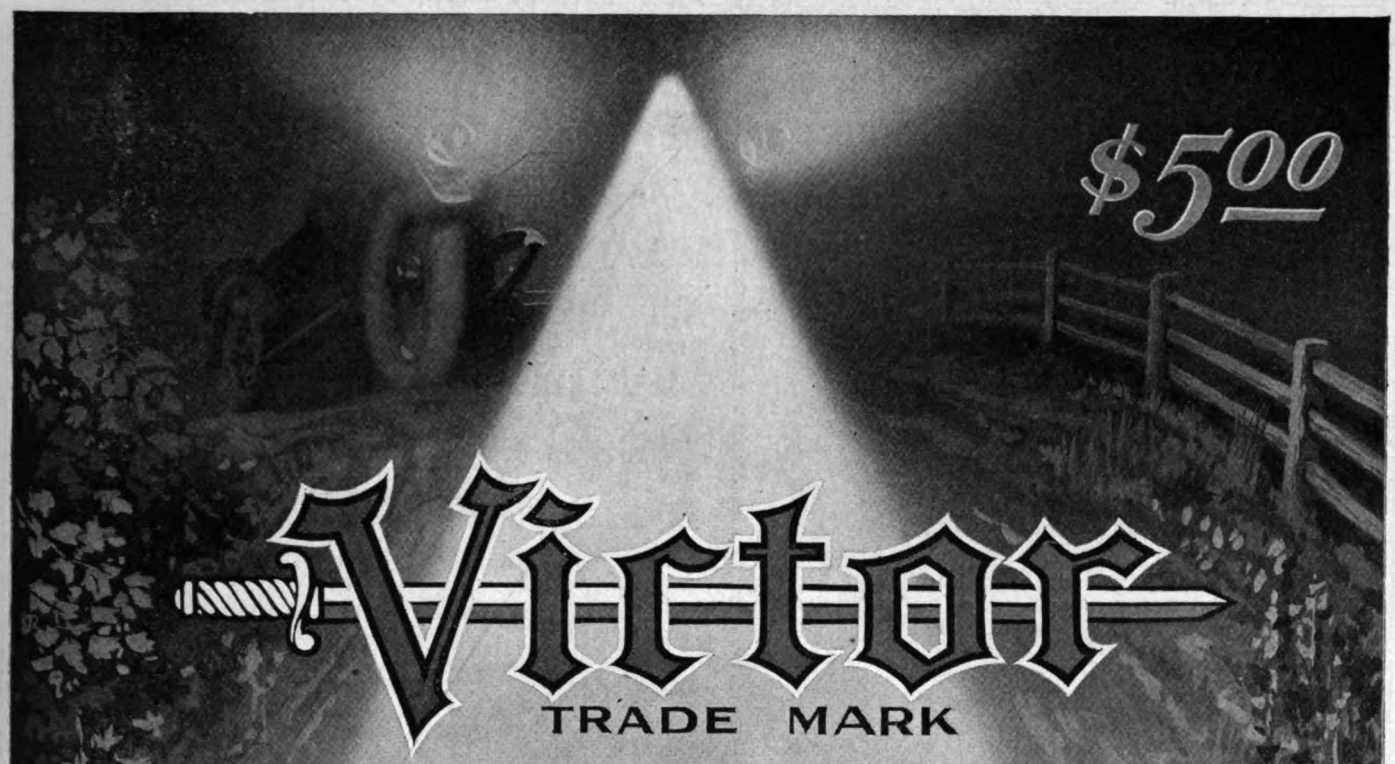
HALLADAY Side Connection Bumper

for cars with expansion aprons or splash pans covering the entire inside of the frame extension.

Adjustable to any frame curve or angle and quickly and solidly attached without cutting or marring the frame or apron.

This is the most nearly universal bumper ever made.

A HALLADAY Display Stand prominently displayed in your store is a silent salesman for your entire accessory line.



Write Us, or Your Jobber, Today for Catalog and Terms.

L. P. HALLADAY & COMPANY, Streator, Illinois

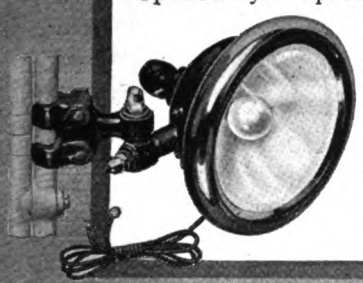
Victor
TRADE MARK

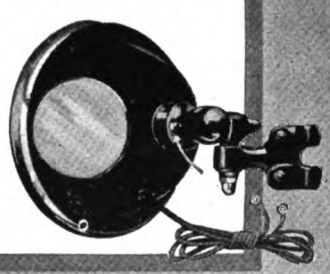


The GREAT SPOT LAMP *regardless of price!*

WHEN you buy a spot lamp to make night driving safe and to enable you to see the traffic behind you in the day time, your first demand should be for quality. Price is only incidental to beauty, durability, simplicity and practical utility.

In beauty the VICTOR has no rivals. Perfect symmetry; workmanship of the highest order; the finest of automobile enameling, nickel door rims and mountings, and a three inch convex condensing mirror inserted in the shell from the inside.

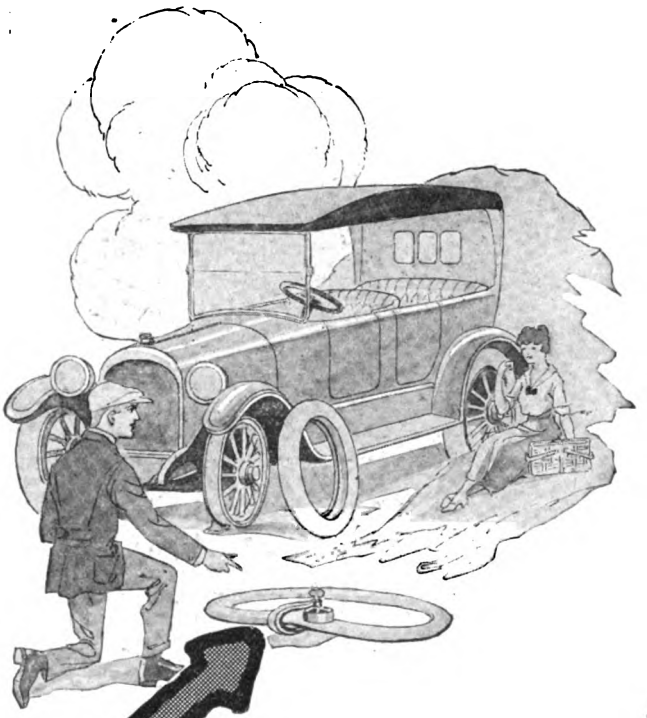
Strength! You see it in the rugged, short shank bracket with double acting knuckles that permit you to adjust the lamp to any angle without imposing undue strain on the frame of the wind-shield.



The doors of the VICTOR are hingeless, dust-tight and absolutely noiseless at all times. They are self-locking but easily opened by the pressure of a single button.

All fastening attachments are carried invisible, on an inner lining. The glass is held secure by spring clamps. It can't fall out when the doors are opened.

The VICTOR is equipped with Mazda Nitrogen Bulb, tremendously powerful and very economical of current. You can change bulbs in about a minute and focus the lamp in half that time. A Cutler-Hammer positive switch and six feet of conductor cord complete the electrical equipment. The world offers nothing better.



Only our enormous production makes our five dollar price possible. Yet you couldn't get a better lamp for twice as much money. This is why you should insist on seeing the Victor Trade-Mark on every spot lamp.

BAILEY
NON-STALL
DIFFERENTIAL

POWER to the wheel that can use it.

A Fundamental Necessity For Every Car

The Bailey Non-Stall Differential *corrects a basic weakness.*
Old style differentials let the power go to waste by sending it to the wheel that does not have traction.
This causes practically all skidding, slipping, stalling, spinning and side-swaying. It is an enormous unnecessary waste of power and tires, and often causes accident troubles and expense.
The Bailey avoids all of this.
With the Bailey no power goes to waste, but *all* of it is used *properly.*
It makes you master of all road conditions.
Anybody can install it quickly. It can be fitted to any rear axle.

Owners and dealers should write us for complete information.
Bailey Non-Stall Differential Corporation, Chicago, Illinois, 1124 Michigan Ave.

It's EASY with a QUIK-EZY

TO CHANGE TIRES ON A SPLIT RIM

The Quick-Ezy Tire Tool with its powerful screw will yank any old rusty split rim apart in a jiffy. It grips at three points and won't bend or slip.

Every garage needs it to give quick service to tire customers and to save time and money.

Every motorist needs it for emergencies on the road.

It's new. *The Quick-Ezy.* Write today for full information.

FIFTH EDITION—JUST OUT!

IMPROVED ONE HUNDRED PER CENT.

Dyke's Auto Encyclopedia.

SEVERAL BOOKS IN ONE.

ENTIRELY REWRITTEN AND ENLARGED—UP-TO-DATE

SOME FACTS CONCERNING THIS ENLARGED 5TH EDITION:

There are 50 **Instructions.**
2370 **Illustrations.**
3 **Supplements** in addition to the 50 instructions, part printed in two colors, treating on the construction, operation, repairing and adjusting of the **FORD, PACKARD** and **KING EIGHT.**
824 pages, large size, 6¾x9¾ inches.
350 pages and 976 illustrations on **Electric Ignition, Electric Starters** and **Generators.**
34 pages and 75 illustrations on the **Delco** system alone.
74 pages and 254 illustrations on **Adjustments, Tests,** etc., of leading **Electric Systems.**
99 pages and 534 illustrations on **Repairing.**
29 pages and 180 illustrations on **Tires** and **Tire Repairing.**
44 pages and 97 illustrations on **Carburetion.**
84 pages and 239 illustrations on **Engines** and **Parts.**
21 pages on **Digest of Troubles.**
4000 lines to the **Index.** This is a feature worth noticing, as it means a ready reference on everything pertaining to motoring.

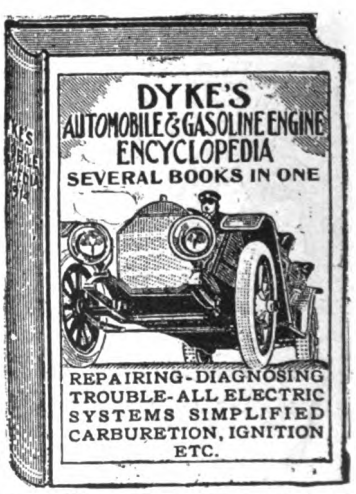
Index is printed on **colored** paper, easy to refer to.

Dictionary is also included, which gives the meaning of motoring terms.

You must see this new 5th Edition in order to appreciate just how complete a book it really is—Order N-O-W.

The Price is still **$3.00** (or **$3.32** postpaid).

How to Become an Expert Automobile Mechanician



The quickest and cheapest, but BEST way, is by studying Dyke's Automobile and Gasoline Engine Encyclopedia.

It is a practical, simplified instruction on everything you want to know and OUGHT to know about motoring.

First you learn the principle of construction of each and every part of a car and engine—then the variance of construction—then the adjustments and repairs.

You learn how to diagnose troubles in a scientific manner. Step by step you advance until you are a *real expert* on timing the valves and ignition, repairing and adjusting. You learn the carburetion subject so thoroughly, you can adjust any make.

You will like this book, in fact we will guarantee you would not sell it for three times its cost if you could not get another.

It's worth ten times its cost if only placed on the shelf and used as a reference.

Beware of Imitators—this is the *original, simplified* book on REPAIRING, ELECTRICAL SYSTEMS, TROUBLES, Etc. It is the only book in the world combining all these subjects under one cover. Why get three—or four books?

Mr. Dyke published the first practical Automobile Book in America.

LIST PRICE — $20.00

This Screw Plate is very popular among Automobile Accessory Jobbers and Garage Men. It is designed to meet the requirements of the Repair Shop and it does to perfect satisfaction. The O. K. Hammered Dies in this set actually cut easier and much cleaner threads made than with the old style dies. This is entirely due to the extra chip clearance and oiling space provided.

Catalog 8-B tells the whole story.

OWN AUTOS

THEY ARE PHYSICIANS

Economical Publicity

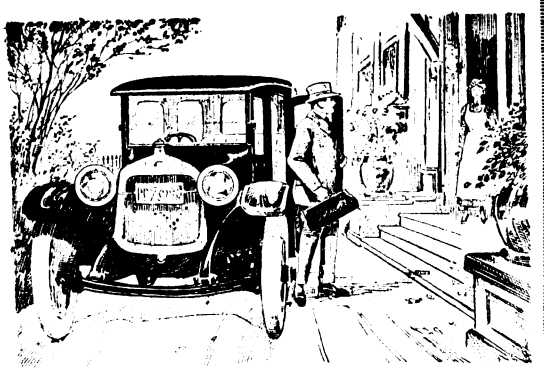
The Journal of the A. M. A. gives manufacturers of automobiles and accessories the opportunity of reaching every week over 50,000 automobile users and over 10,000 prospective owners.

It requires no stretch of the imagination to appreciate the economy of advertising in THE JOURNAL considering that it offers profitable publicity with a minimum amount of waste circulation.

The Automobile a Necessity with the Physician

The automobile with the busy physician is a real necessity. He needs efficient means of transportation which implies a serviceable car and accessories of proven value and standard quality.

Physician a Frequent Buyer



The doctor's average mileage per year is 25,000 miles. He drives in all seasons, every day. In many cases his mileage is higher according to the exigencies of his practice. From this fact he is a frequent buyer.

Professional Paper an Effective Medium

There is no better way to get close to the physician than to appeal to him through the advertising columns of his favorite professional paper.

Attention, Mr. Garageman!

ROMORT TIRE TESTER ATTACHMENT

PRICE, $1.50

This is a device for attaching your gauge to Romort Automatic Air Valve, and gives the service station a permanent holder for its gauge, ready for instant use by the public, eliminating the necessity of loaning gauge to operator, who three times out of five will drive off with your gauge in his pocket.

Attached to Romort Style A Automatic Valve

Simply screw your gauge into this holder and you have a tire tester and tire inflator combined in one, and the old trouble of losing gauge is forever over.

Every garage with free air should be equipped with the Romort Automatic Air Valve and Tire Tester Attachment.

The above price includes the Attachment only.

CAUTION—When ordering, state whether for Style A or B Valve.

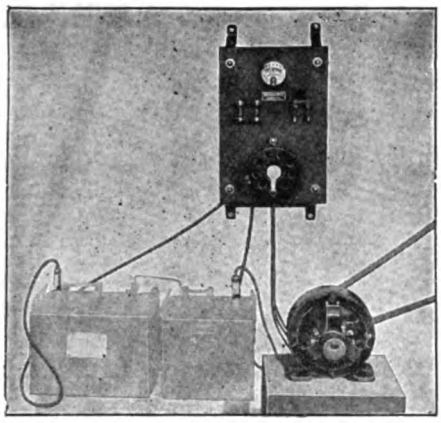
THE KING DRAG

The Great Road Builder

In every part of this great country the **King Drag** can be used to advantage on country roads for putting them into proper shape at a moderate expense. We have brought out a pamphlet which gives full particulars of the use of the **King Drag** and how to make it.

In localities where the sentiment for good roads needs to be worked up, the distribution of these little pamphlets could not fail to do a good deal of good.



We will send **a sample free of charge** to anyone desiring to see it, and will supply the booklet at **a dollar a hundred.**

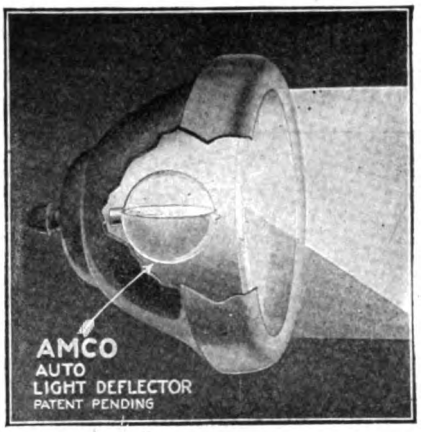
MAIN BATTERY CHARGING SET

No City current is necessary—it generates its own Electricity. Operates from a line Shaft or Engine by belt drive. Charges from *one* to *five* Lighting or Starting Batteries at a time. Any voltage, 6 volts up to 30.



Large profits are made by charging batteries from this outfit, practically all clear profit. Usually driven from power previously installed and in operation, making no additional operating expense. Makes you independent of a lighting circuit and doubles your profits.

Dynamo, high grade, shunt wound, 250 watts capacity, oil ring type bearings, baked black enamel finish.

Slate Switchboard with D'Arsonval type Ammeter, Rheostat, Double Pole, Single Throw Knife Switch, Cartridge Fuses, Irons for mounting, and two large flexible leads with large clips. Properly packed with blue print and complete instructions for operation and care. Price, F. O. B. Pittsburgh, $55.00.

Simple to install, no necessary upkeep. Positively guaranteed. Immediate deliveries. Bulletin No. 42 on request.

MAIN ELECTRIC MFG. CO., Pittsburgh, Pa.

"AMCO"

Is the trade name of the most PRACTICAL, EFFICIENT and LOW PRICED device on the market for the elimination of the "GLARE" of Automobile Headlights.

The "AMCO" is a small WHITE ENAMELED metal cup that snaps firmly on the underside of the lamp bulb, the WHITE surface of the cup deflecting the rays of light to the upper part of the silvered reflector, causing them to be projected Outward and Downward on the road ahead of the car.

The "AMCO" has been licensed by Five States and has received unqualified endorsement from coast to coast. Sold with a positive "MONEY BACK" Guarantee.

SUFFERING FROM A KICK BACK.

You may have no interest in this lady

BUT

any member of your family or anyone dear to you might suffer in the same way.

THE BILL AUTOMATIC SPARK RETARDER

Positively Prevents Such Disaster

by automatically retarding the spark to a point of absolute safety and then advancing it to the normal running point as soon as the crank is disengaged.

The cost is nominal, only

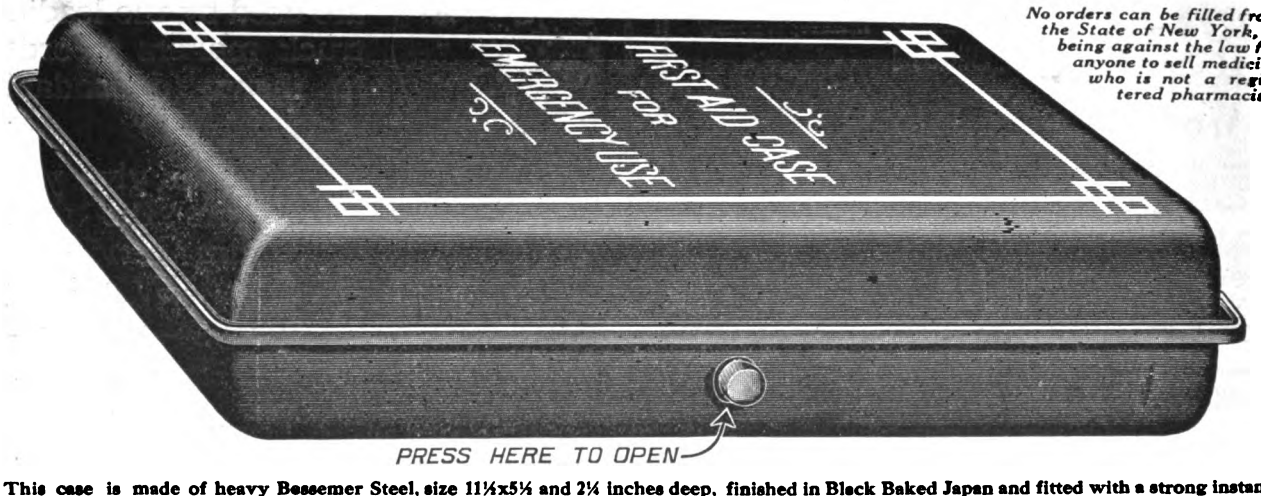
$8.50

Its value cannot be measured in dollars as it is both accident and liability insurance against suffering, inconvenience and financial loss.

If you own a Ford you cannot afford to be without it.

If you are a dealer or repairman it is a profitable and quick selling accessory.

WRITE US OR YOUR JOBBER—TO-DAY.



BILL Mfg. Co., La Porte, Ind. Chicago Distributors: GRAY-HEATH CO., 1440 Michigan Avenue, Chicago, Ill. New York Distributors: ASCH & CO., 16 to 24 West 61st St., New York, N. Y.

IT MAY BE YOUR TURN NEXT

TO MEET WITH AN ACCIDENT ON THE ROAD.

It may also be a case of life and death to have the materials at hand for prompt treatment. We have recently made arrangements for a First Aid Case for emergencies especially for the readers of the AUTOMOBILE DEALER AND REPAIRER.

No orders can be filled from the State of New York, it being against the law for anyone to sell medicine who is not a registered pharmacist.

This case is made of heavy Bessemer Steel, size 11½x5½ and 2¼ inches deep, finished in Black Baked Japan and fitted with a strong instantaneous snap. It is strong enough to resist injury to the contents through accident or dampness.

The contents have been carefully selected to supply the needs in an emergency, before the doctor comes. All gauze, bandages and cotton have been prepared in aseptic laboratories under the same rigid inspection as those supplied to the United States Army and Navy.

The contents of this case consists of:—1 "First Aid to the Injured" Instructions. 1 Yard plain Sterilized Gauze for dressing large wounds. 10 Yards 2-inch Sterilized Gauze Bandages for dressing cuts and bruises. 10 Yards 2½-inch Sterilized Guaze Bandages for dressing cuts and bruises. 1 Package Sterilized Absorbent Cotton for pads and dressings. 1 Box Carbolic Salve for burns, sores, insect bites, etc. 1 Yard 1 inch Zinc Oxide Adhesive Plaster for retaining dressings and covering small wounds. ½ Ounce Tincture of Iodine, an antiseptic for immediate use on all wounds and abrasions. ¼ Ounce Spirits of Ammonia for use in case of shock, heart failure and faintness. ½ Dozen Safety Pins.

The retail price of this outfit is $2.50. We have made an arrangement with the manufacturers of such a liberal character that we can supply this outfit with a subscription to the AUTOMOBILE DEALER AND REPAIRER for a year, for the regular price of the outfit, $2.50.

In case you have already subscribed for this year, we will send you one of these outfits, postage prepaid, on receipt of $1.60, which may be remitted by check, money order, or in any convenient way.

Every subscriber to the AUTOMOBILE DEALER AND REPAIRER should have one of these outfits. It may mean the saving of your own life or the life of some friend. ***ORDER AT ONCE AND THEN YOU WON'T FORGET ABOUT IT.***

STOP YOUR ENGINE OVERHEATING

THE NEW MOTO-FAN WILL PREVENT IT

Efficiency Temperature in your Radiator is from 190 to 195°. Less than that means lost power. More means DANGER.

The New MOTO-FAN is the only cooling device working in connection with the water in your radiator.

PATENTED

The rapidly revolving blades of the MOTO-FAN draw up through a vent on the right hand side of the "ring" the superheated air from the radiator, replacing it with a steady stream of cool air driven in through the "down" vent on the opposite side.

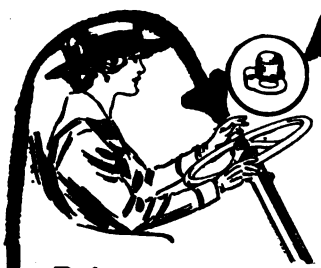
There are several devices for indicating superheated conditions AFTER they arise.

The MOTO-FAN goes one better by forestalling and preventing those conditions.

A ⅜" hole drilled in the radiator cap is the only work required to install the MOTO-FAN.

Anyone who can handle a drill can mount it in three minutes; then goodbye to overheating troubles.

Sectional View.



IF YOU BELIEVE THAT PREVENTION IS BETTER THAN CURE YOU WANT A MOTO-FAN ON YOUR CAR TODAY.

3" wide—3¾" high.
Black, with polished nickeled blades. An ornament as well as a necessity.

LIST PRICE, $2.50 EACH.
(Liberal Discount to the Trade.)

If your dealer hasn't it, write us for descriptive literature.

Motorists Make their own Tire Repairs!

Thousands of motorists who thought they could never repair a tire are now using the Shaler Vul-Kit. They find it easy to mend tubes and casings with this wonderful vulcanizer. They carry it right with them in their tool box and they're always ready for any blow-out or puncture, no matter how far out in the country it happens. With a Shaler Vul-Kit, you can seal the small cuts in time—before sand, dirt and moisture have been pounded into them to rot the fabric and ruin the tire.

SHALER

Vul-Kit For Tubes and Casings **$3.50**

Simple to use. Automatic heat control. No need to watch or regulate it. No chance to overcure or undercure the tire. No exposed blaze or liquid fuel to spill. Seals the cut in the tire with new rubber, protecting the fabric and making the damaged part like new.

Dealers—Write!

Besides the Vul-Kit shown here there are other models of Shaler Vulcanizers for Motorists and Garages from $1.50 up, as well as complete plants for public repair shops. Write on your letterhead for our new catalog.

ALL YOUR GAIN

It Is a Hobby with Some Men to See How Good They Can Make a Thing

IN THIS CASE IT HAPPENS TO BE THE

TESTITE PISTON RING

And a very—VERY Good Ring It Is

Made with an eye single to absolute technical precision. You would hardly imagine it possible that such a supposedly common thing as a piston ring could be made so uncommonly good.

Testite Piston Rings are made in all sizes to fit all motors.

Testite Piston Rings save gas by utilizing the entire fuel charge in the production of power. There is no waste. No loss of power, no waste of exploded gases past piston ring openings.

Testite Piston Rings are a boon to marine, and also to aeroplane motors, where the highest compression is so vitally important.

Testite Piston Rings make your motor measure more power, make it more responsive, and though the highest in efficiency, are the lowest in price for piston rings of their character.

Every ring is inclosed in a separate envelope with directions for installation and are packed twelve in a box for the trade.

Our literature, we believe, treats the Piston Ring question in an intelligent manner—learn more—write us—today—that's better than forgetting it.

THE RED ROAD BOOK

250 Pages. Price, $2.00

—and—

THE AUTOMOBILE DEALER AND REPAIRER

$1.00 a Year

BOTH FOR $2.00

A great many of our subscribers will be glad to know that we have made arrangements with the Bullard Co., of Boston, publishers of the "RED ROAD BOOK," on such favorable terms that we can offer this admirably arranged book, size 9¾ x 9¾, and comprising 250 pages, in connection with the Automobile Dealer and Repairer for a year, for $2.00, which is the regular retail price of the book.

In other words, by subscribing to the AUTOMOBILE DEALER AND REPAIRER, the subscription rate of which is $1.00 a year, you get the "RED ROAD BOOK" AT HALF PRICE.

We don't know of any better book than this on the market. It is bound in flexible cloth, and comprises road maps of the following states:

All of the New England States	Pennsylvania	Virginia
New York	Maryland	West Virginia
New Jersey	Delaware	District of Columbia

These states are largely patronized in the Summer by tourists from all over the country, who like to visit the Catskills, the Adirondacks, and the White Mountains. The "RED ROAD BOOK" also gives maps of that portion of Canada reached by routes from Northern New York, Northern New England and Northern Maine.

It further gives 153 city street maps, to which are added road distance tables, ferry tables, and the necessary population and location indices for all towns.

Reading route matter in connection with the principal routes is tersely told, and will be printed in black, and their reverse routes printed in red, to avoid confusion.

The aim in the production of this work is simplicity. Too many automobile route publications attempt so much, that in their efforts to be "complete" they become "confusing." The publishers of this work say that many years of motor travel and the observations of others lead them to the opinion that once out of the confusion of a city's streets, on the broad highway, the need is less for the detailed, must-be-closely followed printed words, comments and instructions of the path itself, but rather the need is for the accurate knowledge that the road to town A and thence to town B is of "automobile goodness," and that it proceeds via this and that village, this or that side of a lake or a mountain, with crossing railroads, or paralleling trolley lines, as a check on location.

Thus is one free to carry out his original purpose; namely, to see the country, with this instruction book.

If with such maps as are shown in this road book, one sees that they are to pass within a few miles of a well-known and picturesque lake, or historic hamlet, or perhaps desire to go "across country," a good road map is the best aid for this free lance mode of travel.

A new edition of this road book is now being prepared, and will be corrected right down to date, and will contain much new material. The book will be ready for delivery from the first to the fifteenth of April.

All orders sent to us will have prompt attention just as soon as the book is issued. In case you have already renewed your subscription, a Red Road Book will be sent on receipt of One Dollar Address:

The Oster Mfg. Co.
2102 East 61st Street Cleveland, Ohio

The Pennock Headlight Tilter

Operated from the seat, best covers all the conditions of city and country driving with 40 to 300% more light than other devices.

Don't cover up your light with lenses, you need it all. **Don't turn out your light with dimmers,** when you need it most.

Tilting **increases** the light in proportion to the decreased distance lighted, **absolutely eliminates glare** and is legal everywhere. Fits electrically lighted, gas lighted or Ford cars. Retails at $5.00 the set. *Write*

Builders ... All-Geared ... Gap Lathes

Supreme Upholstery

When a dealer or manufacturer sells you a car upholstered in Du Pont Fabrikoid, Motor Quality, he sells you something infinitely superior to the average so called "genuine leather" or coated "splits". He gives you a standard material—standard in quality, service, appearance and wear. A scientifically constructed leather-like fabric twice as strong as coated "splits."

DU PONT FABRIKOID

REG U. S. PAT. OFF.

Motor Quality

has all the artistic beauty and looks of the finest leather with none of leather's faults. It is water, dust, grease and stain proof and sincerely guaranteed.

It comes in standard rolls and standard widths. It saves the car *manufacturer* time, labor and expense, because it can be cut in mutiples and eliminates waste. It guarantees each car purchaser better satisfaction because it gives greater service.

Write for Samples and Booklet.

Add $250.00 A MONTH EXTRA To Your Business

REPAIR AUTOMOBILE TIRES

Sounds like a whole lot of money to clear extra every month. Seems almost impossible, but that is what hundreds of men are doing who have added a Tire Repair Department to their business. **The investment is small, the profit large** and **returns quick and all cash,** besides the demand for tire repairing and retreading is constantly growing. Your garage is by no means complete, your business is not as profitable as it can be until you get in on the Tire Repairing and Vulcanizing end.

THE HAYWOOD TIRE REPAIR EQUIPMENT

Answers all the requirements to successfully handle this end of the business. With it and a little business judgment, success is certain. Every year adds thousands of new auto owners. They are looking more and more to economical tire service. The day of discarded tires is over, the Haywood Equipment makes this possible.

HERE IS YOUR OPPORTUNITY

Either as a side line to your present automobile business or as a business by itself, the Haywood Equipment will make money for you. **Tires go wrong all the time.** You know that. Keep them in tune. Give your customers complete service—repair their tires and all. This builds business and makes you rich. Experience unnecessary. You can learn easy—or teach a boy to handle this end. Be the boss and make the money. Learn the details now. Investigate. Act quick. Be the first. Send name and address only. A postal will do.

HAYWOOD TIRE & EQUIPMENT CO.
965 Capitol Ave., Indianapolis, Ind.

FOX TYPEWRITERS

Factory Rebuilt Like New at $65.

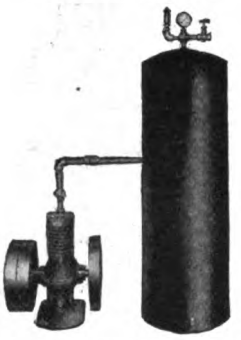
The word "rebuilt" has been abused and misused until it has become a meaningless trade term. When we rebuild a Fox Typewriter we take it all to pieces, re-nickel the nickel parts, re-enamel the frame and replace all worn parts with new ones. The same men who originally built the typewriter do this rebuilding **and do the work just as good.**

50% NEW PARTS AND 3 YEARS GUARANTEE

We offer a rebuilt Fox Typewriter, Model No. 24—*just like new*—for $65.00. These have standard carriages taking paper 10½ inches wide, any kind of keyboard, any kind of type, rubber covers, tabulators, back spacers, two-color ribbons, and are complete with instruction books and cleaning outfits.

Send us any amount you can spare, **from $1.00 up,** as a first payment, and pay the balance $5.00 monthly. Or, send $61.75 all cash. If $10.00 or more is sent with order we will include Free our $4.50 Solid Oak Typewriter Table. Transportation must be paid by the purchaser.

Please order direct from this offer, mentioning Automobile Dealer and Repairer for January. State price you wish to pay and enclose any amount of cash you can spare.



FOX TYPEWRITER CO., 6201-6211 Front Ave., GRAND RAPIDS, MICH.

"THE RETURNS"

that we get from our Advertisement in "THE BLACKSMITH & WHEELWRIGHT"

— ARE GOOD — VERY GOOD !!

NO matter what kind of Auto Equipment you manufacture, you ought to advertise it in "The Blacksmith and Wheelwright." These "Smiths" and "Wrights," all over the country are now Repairing Autos and Selling Auto Goods. They seldom or never get a look at an Automobile Journal—but they do swear by every printed word they see in their tried and true friend, "The Blacksmith and Wheelwright." They are on the keen edge to know what auto equipment men have to sell—and they buy.

"The Blacksmith and Wheelwright" is the oldest journal of its kind in the world, having been published for more than 37 years under the same ownership and management, and recognized as a leader in its field.

Light Weight Piston for FORDS

MORE SPEED

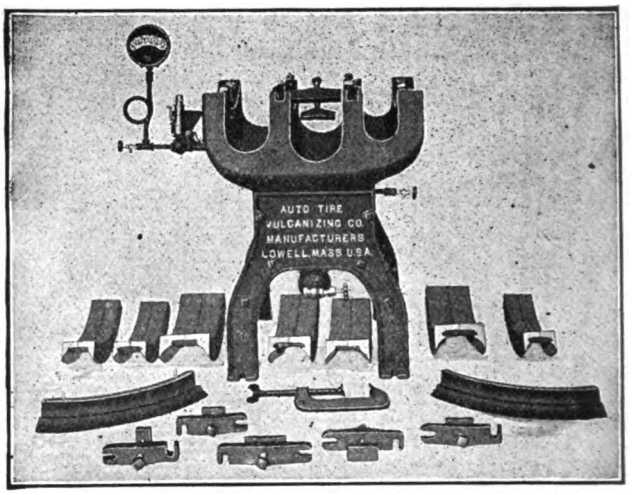
LESS VIBRATION

Weight 1 Lb. Less Than Standard Ford

Manufactured to the Limit of 2 Ounces Variation in Weight

A PISTON AS FINELY MADE AS THOSE USED IN THE HIGHEST PRICED CARS

A reduction of 4 lbs. weight on reciprocating parts saves a tremendous percent of crankshaft and wrist pin bearing wear.



The DYER LIGHTWEIGHT PISTON for FORDS possesses all the ADVANTAGEOUS features of alloy and aluminum pistons without their BAD FEATURES such as slapping, oil throwing, seizing and poor compression and COSTS BUT LITTLE MORE THAN STANDARD FORD PISTONS.

This piston is tough, durable, absolutely round, perfectly machined, has a domed head, uniform walls and special oiling features.

Standard or overs; $1.75 each (complete)

Inquire of your jobber or write us for latest catalogue.

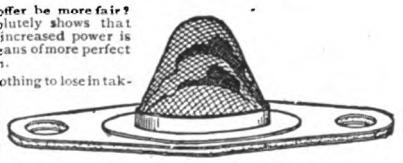
GASCO

GASOLENE ECONOMIZER

NOW—IT'S UP TO YOU!



Truth is never crushed to earth if given a square deal. Pin a dollar bill to your letterhead—mail it to us and prove Gasco's distinguishing traits.

First, determine the speed of your motor while idling and with the throttle all the way down.

Then unbolt the carburetor flange from the intake manifold and insert the Gasco as if it were a gasket, tighten up the bolts and start up the motor.

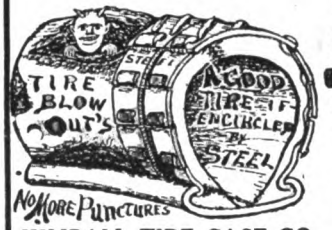
If the motor doesn't run faster than it did before, just send the Gasco back and we'll refund your money.

Can any offer be more fair? This test absolutely shows that with a Gasco increased power is obtained by means of more perfect fuel combustion.

You have nothing to lose in taking advantage of this offer, and you can readily prove for yourself that Gasco will save its cost in a short time in the saving of fuel, besides adding power, reducing carbon, and preventing fire due to backfire.

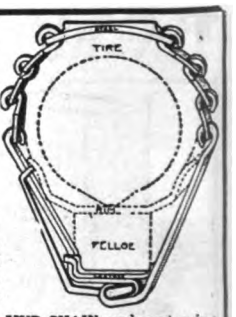
Thousands sold—one large concern purchased 3200.

Dealers everywhere find it a quick seller and a good profit-producer. Our sales plan calls for a small investment and gives a quick turnover. Write today for particulars.



GASKET SUPPLY COMPANY

17th & Ludlow Sts. Philadelphia, Pa.



Mfrs. of Gaskets, Packings, Washers, Stampings, Punchings and Dies.

Hang on to your old tires. They will last as long as you live if covered with steel. **The Kimball Steel Protector** makes **Blowouts, Punctures** and **Rim Cuts** impossible. A few sections will hold any old blowout. Tires as flexible as ever.

Special inducements to those in new territory.

MUD CHAIN can be put on in a jiffy with one hand while standing on the run board. If you get in a mud hole you will laugh out loud. Hook the ends together and pull the little lever and they are on tight. Good for blowouts.

THE HEISER IMPROVED CYLINDER REBORING TOOL for Ford Motors is the only Reboring Tool in the world that is self sharpening. It is the only Tool except expensive grinders that will not leave the finished cylinder slightly tapered toward the bottom. It is the only Tool that rebores between centers—this insures a finished cylinder, square with the crank shaft, round, straight and true. It is adjustable, and the only Tool that will rebore different sizes without losing the adjustment.

The best mechanic in the world can't build reputation without proper TOOLS and EQUIPMENT. THE HEISER IMPROVED CYLINDER REBORING TOOL MAKES GOOD SHOPS OUT OF POOR ONES AND BETTER SHOPS OUT OF GOOD ONES.

Write to-day for full particulars

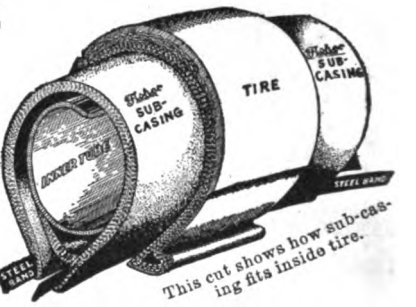
THE Fisher PATENTED "RIM-GRIP" SUB-CASING

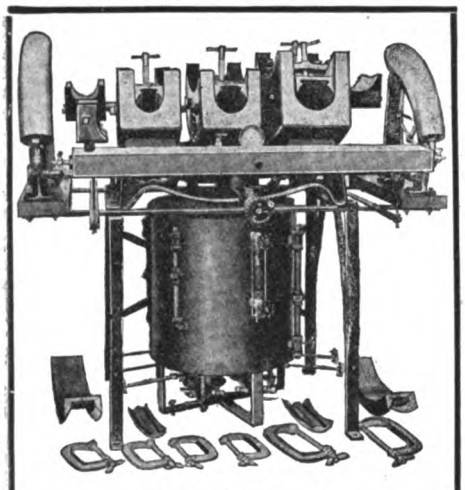
MORE MILES PER TIRE LESS TIRES TO BUY

THE BLOWS THAT YOUR TIRES RECEIVE, WHEN YOU STRIKE OBJECTS IN THE ROAD, LEAVE WEAKENED PLACES IN THE FABRIC.



A TIRE IS AS STRONG AS ITS WEAKEST PLACE

These weakened places are hard to detect now, but will result in blow-outs later.



RIM-GRIP SUB-CASINGS reinforce the fabric of the tire at all points from bead to bead. They make a partially worn tire stronger than it ever was. It can be worn out completely and the sub-casing used in another tire. As the cost of equipping a car with new tires is much greater than last year, it will pay you to investigate Rim-Grip Sub-Casings. *Write for particulars.*

FISHER MANUFACTURING CO.

1706 PAYNE AVENUE, :: :: CLEVELAND, OHIO

This cut shows how sub-casing fits inside tire.

THIS YEAR'S AMERICAN HOTEL DIRECTORY

YOU CANNOT ASK US A QUESTION ABOUT ANY CITY AND HOTEL OF THE WESTERN HEMISPHERE THAT WE CANNOT INSTANTLY ANSWER. WE WANT TO ASSIST YOU IN PLANNING YOUR ITINERARY OR ROUTING YOUR TRAVELING REPRESENTATIVES. LET ONE OF US BE YOUR PRIVATE BUREAU OF INFORMATION.

HOTEL EDITION, $3.00—That's the big brother, he knows as much as all the rest of the family put together. He is built for heavy work and rough usage at big hotels. He's informed on everything but the time table" on North and South America, from Bermuda to Hawaii inclusive.

COMMERCIAL EDITION, $2.00—Knows just as much as his big brother, but not so strong, designed for smaller hotels and commercial offices, where he won't have to work so hard, still, with reasonable, careful use, he's long lived.

UNITED STATES EDITION, $1.50—A fine investment for any one who doesn't go outside of the United States, but when it is within these borders, you can't stump him with a reasonable question.

BRITISH AMERICAN EDITION, $1.00—This chap has completed a tour of all Canada, and the British American Islands, he knows all about these parts and the hotels.

LATIN-AMERICAN EDITION, 50c.—A little fellow to be sure, but still full of information about everywhere and everything fit for a white traveler to go or see in the Southland—from El Paso to Cape Horn.

POCKET EDITION, 50c.—The little book with the big circulation, designed for the traveler and his hand bag or coat pocket. Lists the principal cities, principal hotels, and points of interest in United States and Canada only.

All illustrated, printed on strong paper and cloth bound.

Either of the editions referred to above will be sent to any address on receipt of price. We would particularly recommend the **Pocket Edition** at **50 cents**; as it will answer for the most part all practical purposes. Postage stamps accepted in payment. Address:
MOTOR VEHICLE PUBLISHING CO., 71-73 Murray Street, New York.

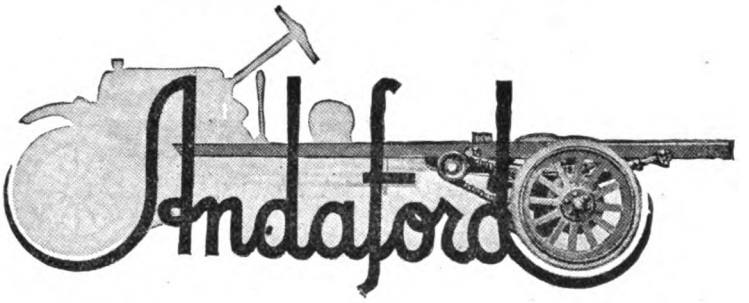
A POPULAR MOVIE.



MORAL FOR DEALERS

Success in business means vision to realize a Public Demand and being prepared to supply it.

$295.00

Lowest in Price Biggest in Value

"And the little old Ford it rambled right along" says the song, a tribute to Ford efficiency and durability. Millions of Fords, now rambling as pleasure cars, will continue to ramble in the future as sturdy, dependable, 2500 pound trucks.

Business men are awakening to the fact that it is folly to buy a new truck or do without, when a Ford can be so easily and quickly converted into a first class 2500 pound truck, at such a surprisingly low cost. There's a good, profitable harvest in this field for live dealers.

The Actual Market

The demand for trucks of this capacity is enormous and certain. The money saving inducement for the merchant in being able to secure so easily a truck with the well known efficiency of the Ford, means a money making proposition of stupendous proportions for dealers. No need to develop a market. It is ready and waiting.

The Potential Market

The future needs for small trucks can hardly be estimated. When trucks can be procured at so low a cost, thousands of uses will be found for them, which are as yet unthought of. Your imagination can run riot along this line without exceeding the possibilities. The low upkeep of the Ford will result in fleets of Ford Trucks replacing the heavier kind, etc. Be ready for the harvest.

Why The ANDAFORD

The ANDAFORD attachment, composed of chassis, heavy artillery rear wheels, springs, chain drive, etc., made to attach rigidly to original Ford chassis by simply removing pleasure car body and rear wheels, is designed by men associated with the auto industry ever since it was an industry. In construction, utility and quality of materials it is supreme, and the price—$295, will make it a ready seller. Limited space prohibits lengthy description, but suffice to say, facility for enormous production enables us to turn out the biggest value on the market at the lowest price, with a profit to dealers that we know will interest you.

Your Best Interests

demand looking into the money making possibilities of the ANDAFORD. Get into this profitable field now.

The spark plug that is standard equipment for U. S. Army and Navy airplanes—

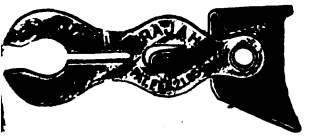
the spark plug that brings the majority of racing cars first under the wire—

the spark plug that is found in Duesenberg and Seabury "Speedway" motors—

is the spark plug for the dealer who wants to make the most sales to the owner who wants the most power in his car.

RAJAH
SPARK PLUGS

Because Rajah Spark Plugs are built sturdy enough to withstand the test of racing cars, speed boats and airplanes, they give the automobile owner dependable power with a big margin of endurance.



Because Rajah Spark Plugs are fairly priced and extensively advertised, they give the automobile dealer dependable sales with a big margin of profit.

That is why Rajah Spark Plugs are so popular with dealers and owners alike.

Address RAJAH, *Bloomfield, N. J.*

HUGHSON & MERTON, Inc., San Francisco, Los Angeles, Portland, Seattle

X-Ray View of the Wonderful Howe Bracket that turns any direction as easily as you point the finger. Puts the Howe Spotlight in the "Safety First" family.

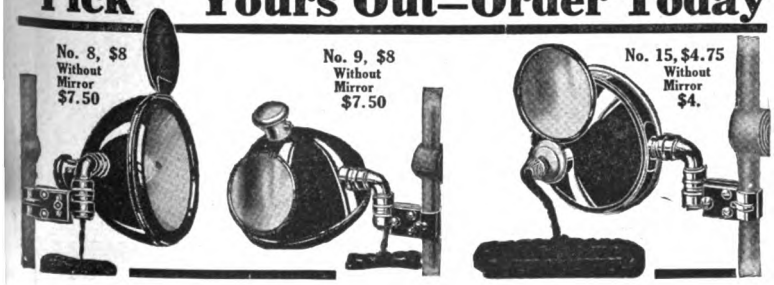
Light Quick—Anywhere it's Needed —Around the Automobile

Light that explores the bad turn—that makes safe the passing on a narrow road, that tilts downward to give a powerful road light without glare, that provides a wonderful trouble lamp—these and a hundred and one other uses make the Howe Spotlight a necessity. The value of a spotlight is in direct proportion to the efficiency of its bracket. The Howe Bracket is a wonderful combination of ease of action with positive firmness. It permits an easy turn *direct* to the spot you want to see. It *holds* the lamp firmly right *where* you turn it. Road shocks and vibrations won't move it. The patented coil springs, acting on the turning joints, are the secret of this *gentle* firmness. They take up all jar and loose motion—insure perfect service always.

HOWE Searchlight

"The Spotlight with the Wonderful Bracket"

The wonderful Howe Bracket also contains and protects the wires—prevents flopping, wear, and short circuits. ***The Howe is always in focus—gives a perfect Spotlight at all distances.*** Outlines objects a quarter of a mile away. The switch is "on and off type"—right in the neck of the handle. You light up with the same motion that you turn the lamp. One of seven 2-piece Howe clamps insures a perfect fit for every windshield frame. The finish is baked-on enamel—good as that of the car.



Be Sure Your Spotlight Is a Howe

If your dealer hasn't it, accept no other. Remember, a spotlight is only as good as its bracket. ***Only*** the Howe has the wonderful spring controlled bracket. Send remittance for the Howe Lamp you want, telling the make, model, and year of car you drive—for a Howe Lamp prepaid. Be sure to give your dealer's name.

Dealers: The Spotlight with the wonderful bracket makes the best buy—it's the big seller. You ought to have it ***now.*** Wire for a dozen, mentioning jobber's name.
Display stand, attractive circulars, and other live selling helps furnished without charge. Write for full particulars.

From the Land of the Kangaroo

"QUALITY", said a shrewd Yankee merchant, "will carry your goods further than craft". The pun may be poor but the sentiment expressed is very much to the point.

Quality has carried Texaco Products a long way. On the other side of the world they are as well known as they are here at home.

Recently the following letter, forwarded from far-off Australia, was received at our New Your office. It is a proof of the reputation established in the land of the Kangaroo by

TEXACO MOTOR OIL

THE JUNCTION GARAGE
Scheps Bros.
MOTOR ENGINEERS AND IMPORTERS

Melbourne, February 18th, 1916

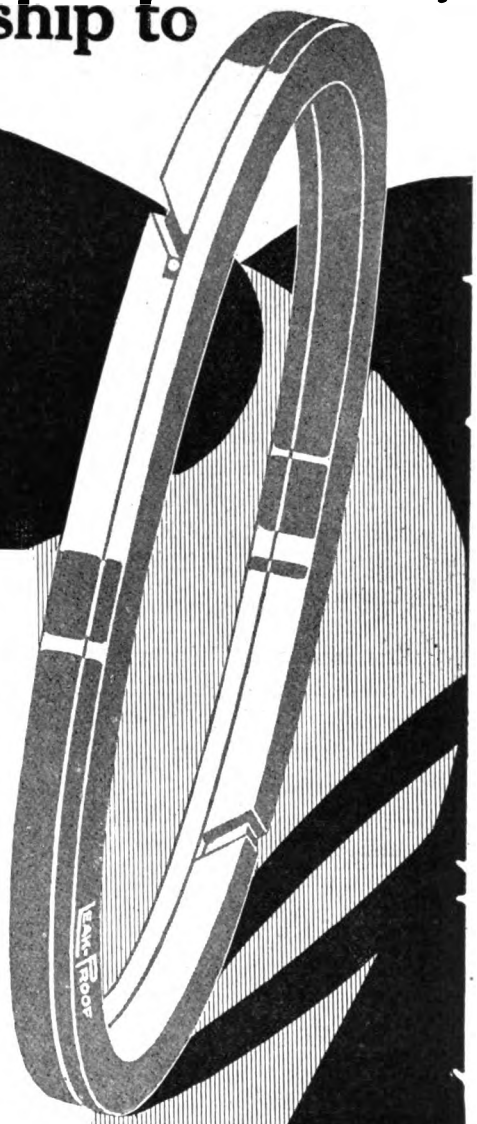
Mr. J Norman Parker
c/o Messrs. R. W. Cameron & Co.
Queen Street, Melbourne.

Dear Sirs:

Kindly send us per carrier 5 barrels Texaco Motor Oil E. H. and 2 barrels ditto No. 2 "M" as supplied to us previously. If your principals maintain the high quality of these oils you may count on us for regular requirements as we have used these in our own cars, one of which we had down for inspection last week after 20,000 miles running, and this car showed absolutely no signs of carbonization in the cylinders, or on the pistons, hence the above order.

We are using Texaco Motor Spirit almost exclusively, and we are very pleased with the quality.

Yours faithfully,
SCHEPS BROS. *(Signed)* Fred Scheps.



There is a garage near you that supplies Texaco Motor Oil. Try it. The safest way, the best way, to buy is in one or five gallon cans. You can identify Texaco by its clear, clean color.

Six Facts that Give Leadership to

McQUAY-NORRIS LEAK-PROOF PISTON RINGS

Most Efficient—because the ring is designed in the only way that can insure equal bearing on the cylinder wall without wasteful friction.

Most Durable—because the processed gray iron used is made to our exclusive formula and is exceptionally strong, elastic and long wearing.

Best Known—because the education of the motorist on piston ring service was started by the McQuay-Norris Mfg. Co.—makers of the Genuine LEAK-PROOF Rings.

First Advertised—for five years national advertising has built up prestige and confidence that makes them sell.

Largest Range—covering every size and over-size, both in widths and diameters—for every make, model and type of motor or engine.

Greatest Distribution—over 300 jobbing and supply houses carry complete service stocks. Any dealer can get the exact size ring he needs in twenty-four hours.

Bring this leadership into your piston ring replacement or accessory business. It will guarantee easy selling, satisfied customers and increased profits.

OUR FREE BOOK

"To Have and to Hold Power" tells all the story. You should get and read it. Write Department R.

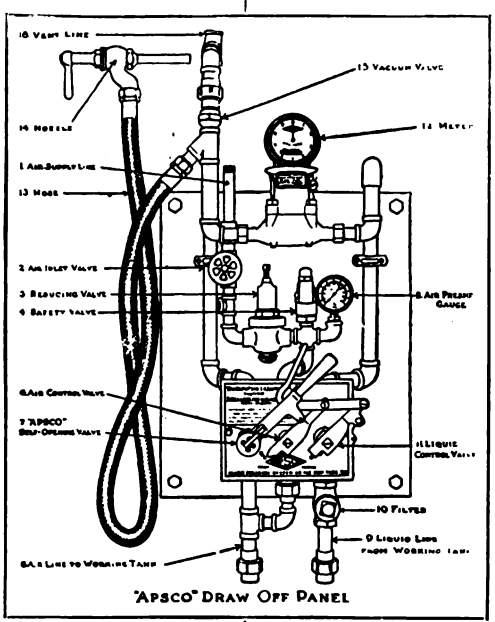
Gasoline by Air Pressure

The New Way—The Safe Way



Safety: An important feature of the APSCO System which has gained for it the approval of the National Board of Fire Underwriters is its safety against fire.

This system for storing and distributing gasoline, oil, or any other volatile liquid is so constructed as to eliminate the possibility of ignition or explosion.

Economical: Economy of operation is assured. There is no opportunity for the liquid to vaporize or gases to collect—full strength and quantity of liquid is certain, because it cannot be left running, nor is it exposed to the atmosphere at any point within the system.

Permits: The approval of the National Board of Fire Underwriters means not only safety in operation, but assures lowest possible fire insurance rates, at the same time tending to obtain the co-operation of local authorities in the matter of permits and approvals.

Tested: The APSCO System is not an experiment—It is a demonstrated success, in actual operation in many garages and mercantile establishments, where it is daily giving marked satisfaction.

Accurate: The Special APSCO meter tells at a glance the amount of liquid drawn off—a meter tested and sealed by the Bureau of Weights and Measures of the City of New York.

Speedy: Speed of delivery is at times a vital factor, and the APSCO System meets all requirements in this regard.

No Labor: To operate the APSCO System you simply pull a lever. No labor is required; a small amount of air pressure does the work. There are no complicated cranks or other laborious devices to bother you.

Lift: Delivery on the third, fourth, fifth, sixth or any other floor is just as easy for the APSCO System as on the ground floor. The system is quickly and easily adapted to varying conditions of height, distance or speed of delivery without in any way affecting the accuracy or safety of the system.

Service: In a word, the APSCO System is economical, safe, speedy and accurate. The multi-storied garage, or the smallest, needs this truly efficient labor-saving, time-saving, money-saving system. Our staff of experienced engineers is ready at all times to co-operate to the fullest extent.

10,000 MILE GUARANTEE Backs This Tire

Every Brictson Pneumatic Tire is sold under a specific 10,000 miles written service guarantee. This guarantee is the ***longest*** and the ***strongest*** ever put behind a pneumatic tire. It is the result of ten years' experience and is a positive protection to every purchaser. Try Brictson Tires on your car at our risk and learn how to cut down your up-keep costs.

"ABSOLUTELY PUNCTURE PROOF"

Brictson Tires are puncture-proof, blowout proof, skid proof, rut proof, rim cut proof, oil proof and gasoline proof. Wonderful resiliency and easy riding qualities as well as economy commend them to car owners. The service and satisfaction they give is rapidly extending their sale.

Retread Your Present Tires

If your present tires are new you should by all means apply Brictson Treads, or tire protectors, thereby making them puncture proof—rut proof—rim-cut proof—gasoline proof and non-skid.
If your present tires have been used and the rubber tread has been worn off or thin, you may get additional service by applying Brictson Treads, also making them puncture proof, oil proof, rut proof, gasoline proof and non-skid.

Free Trial Offer

To convince you that Brictson Tires will give you satisfaction we will let you try them on your car at our expense. Write today for conditions of this Free Trial Offer and full information about Brictson Tires and Brictson Treads.

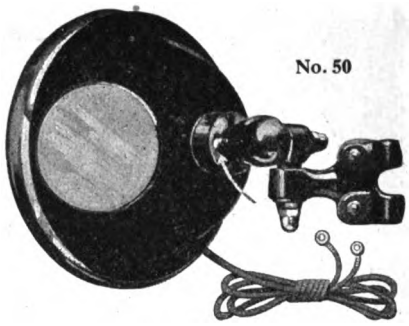
Six exceptional features make the

Victor

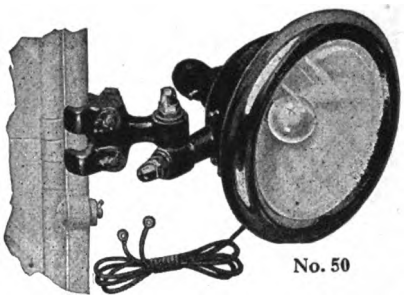
TRADE MARK

THE BEST SPOT LAMP EVER PUT ON A CAR!



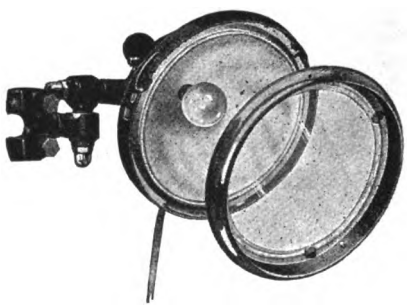
Once you have experienced the joy of reading sign-posts, finding your way easily into the garage, discovering mud-holes and ditches at night, and watching traffic in your mirror by day, you will think Victor safety and convenience wonderfully cheap at—

$5.00



The exceptional Victor features are—

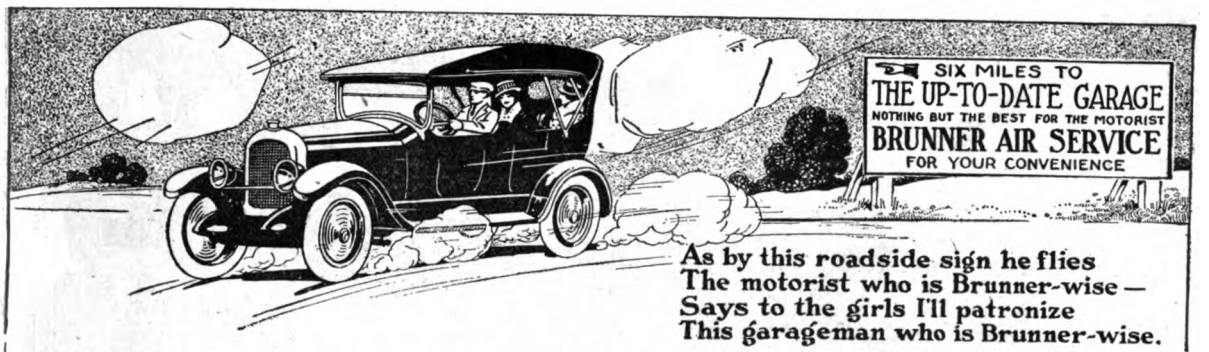
1. A hingeless, dust-proof, nickeled door that is securely locked, but released in a second by pushing a button.
2. Reflector that insures a perfect focus of the bulb.
3. A short-shanked bracket that fits any windshield support, holding lamp securely in any position.
4. A lamp socket that enables you to change and re-focus bulbs in two minutes on the darkest road.
5. Cold drawn steel body, finished in black enamel with 3-inch condensing mirror, to show traffic behind you as you drive.
6. Cutler Hammer positive switch inserted in handle, and six feet of conductor cord ready for immediate installation in any car



Don't postpone the greater comfort you'll take with a VICTOR!

Note the Cutler Hammer Switch right where your fingers can touch it when you adjust the light.

Note the unrivaled neatness of the rounded dust-proof nickled door, which is well in keeping with the headlight doors.



The door is shown turned over. Note lugs holding glass in place. Note cord entrenched on flange of the reflector. It presses against the glass when the door is on, and keeps lamp from rattling.

Look for the Victor trade-mark on every spot lamp.

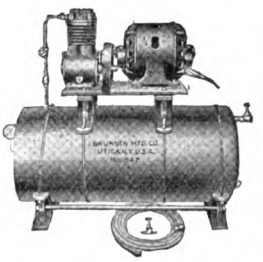
As by this roadside sign he flies
The motorist who is Brunner-wise —
Says to the girls I'll patronize
This garageman who is Brunner-wise.

Mr. Garageman, is your garage up-to-date? Are the Brunnerwise Motorists spending their money with you, or are they spending their money with the Brunnerwise Garageman down the line a ways who advertises the fact that he is supplying prompt and efficient service by displaying the Brunner Sign on his garage?

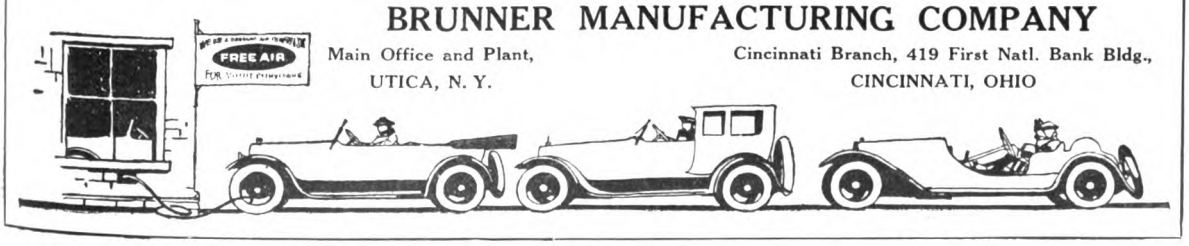
If your business is not so large but that you could handle some more, Mr. Garageman, you should investigate Brunner Service—



The Brunner Sign Attracts the Trade of the Brunnerwise Motorist

WE USE A BRUNNER AIR COMPRESSOR
FREE AIR
FOR YOUR CONVENIENCE

The Brunnerwise Motorist is a most discriminating individual, he appreciates good service and he knows prompt and efficient service always awaits him at the door of the garage displaying the Brunner Sign. He is a liberal spender and spends his money with the Brunnerwise Garagemen who show him that they have his interests in mind by installing Brunner Service.



The Brunnerwise Garageman is reaping the benefit of the good advertising derived from the Brunner Sign, for his garage is the stopping place of the Brunnerwise Motorist who always patronizes the garage displaying the Brunner Sign, because he knows he can depend on real service when he stops to trade with the Brunnerwise Garageman. Are you Brunnerwise?

INVESTIGATE THE BRUNNER AIR COMPRESSOR

Be honest with yourself and investigate the garage air compressor question thoroughly before deciding on your new equipment. The Brunner will stand investigation and the more thorough the investigation the more certain will be your decision in favor of Brunner Service, because it not only insures compressed air efficiency of the very highest order, but it also insures that very desirable and liberal patronage of the Brunnerwise Motorist, which follows the Brunner Sign.

We will be glad to send you the name of the Brunner Jobber who covers your town, also our catalogue and Garageman's Handbook on Compressed Air—a book which every garageman should read carefully. They are all free for the asking.

The Motorist's Ambition

Isn't it the ambition of every motorist to feel that his grip on the wheel makes him master of the road? He doesn't want to race, but isn't it a joy to know that when Bill Smith tries to pass him he can let 'er out and give Smith the Ha, Ha? He buys a car for convenience, but it isn't that which increases his chest measure an inch or two and makes him crow—"Why, I took that old Bluff hill on high and never phased my little old bus. She's some car, believe me!"

He doesn't want a car for exhibition purposes, but isn't it a grand and glorious feelin' to know that when his sporting blood does crop out, his car will respond and preserve the honor of the family?

Isn't his happy brag the kind of advertising you want and the car you want to sell? Does a red-blooded man quarrel about price when he has tried out a car like that? Help him to realize his ambition.

That Kind of a Car

was what the Ross designers had in mind when they turned out their masterpiece They didn't try to build what the motorist says he wants (when the wife is listening), but what they know he does want, whether he be a college boy or banker of 60. That's why the Ross hits the real vital spot in human nature.

WHY NOT GIVE HIM

The Importance of Balanced Design

What is the reason for the speedy acceleration, the marvelous control, the ease of handling, the life and gimp of the Ross? It is not all in the motor. It's in the way the car is designed to utilize every ounce of energy in the motor and harness it for service. It's easy to get speed or some other desired end by sacrificing something else to get it, but to make a perfectly balanced car requires ingenuity. Perfect balance between motor and car is what makes the Ross a joy to its possessor, and him an unconscious booster of the dealer who sold it to him.

ROSS

The Balanced Car

$1750.00

For 7 Passenger, 4 Passenger Suburban Type or 3 Passenger Roadster

WHAT HE WANTS

Looking Down the Road

Every dealer is driving down a road seeking to reach the destination of success. He sees his goal ahead and steers as straight for it as the stones, ruts and curves of business will permit. His speed will be handicapped or hastened according to the car he has selected to carry him toward his object. The right kind will level the hills, ease the jolts and carry him forward with the least strain on his physical, mental and financial resources. That car must have the strongest appeal to the motorist.

Ironing Out the Hills

A Ross with a load of 1,103 pounds (7 passengers) climbed Lookout Mountain, Colorado, officially locked in high, at an average speed of 20 miles per hour.

A Ross traveled 1,000 miles, from Detroit to Topeka, over all hills and all kinds of roads, in heavy rains and thru deep mud, without shifting from high even when starting car. One 45% grade had stumped many cars on low, but the Ross ate it up and gained speed in the ascent.

A Ross recently followed the band in a parade on high gear, and at the conclusion of the march the motor had not heated in the least.

A Ross won $100 in a Milwaukee hill climbing contest by easily taking Milwaukee's worst hill (19th Street) on high, loaded with passengers.

A Ross climbed the famous Filmore Street hill in San Francisco, chained and padlocked in high, and finished at 20 miles per hour, a feat never before accomplished by any car.

And so it goes. We can show newspaper clippings of these and many other like performances that characterize the Ross car.

Is that the kind of car you want to sell?

Speed 'er Up

Speed up your business by adopting the Ross—the Balanced Car, as your business booster. Let's get together and discuss the proposition. Send the coupon today.

Six Styles

each designed and constructed with **Study, Experiment, Test and Experience**—to meet in every way the requirements of present day motors.

No one plug can possibly fit every engine—so there are six styles of

MASTER CALORITE SPARK PLUGS

Master Calorite Spark Plug Regular Length, $1.00 each

The engineers responsible for the manufacture of Master Plugs—with years of experience in the manufacture of Spark Plugs and Spark Plug Parts, thoroughly conversant with present motor car requirements and ignition demands—have persistently kept Master Calorite Spark Plugs up to the minute in:

Quality of materials. Potential resisting power against strains from sudden, violent temperature changes. Improved design. Thoroughness of testing. Sturdy construction and excellent workmanship—justifying the claim that they exemplify the highest achievement in spark plug construction.

Their plainly evidenced quality has been a a shield against any degradation to the cut price class.

Our Liberal Guarantee ["We guarantee Master Calorite Spark Plugs against all defects of material or workmanship and will replace free of charge any Calorite insulators broken by heat which are returned to us transportation prepaid."]

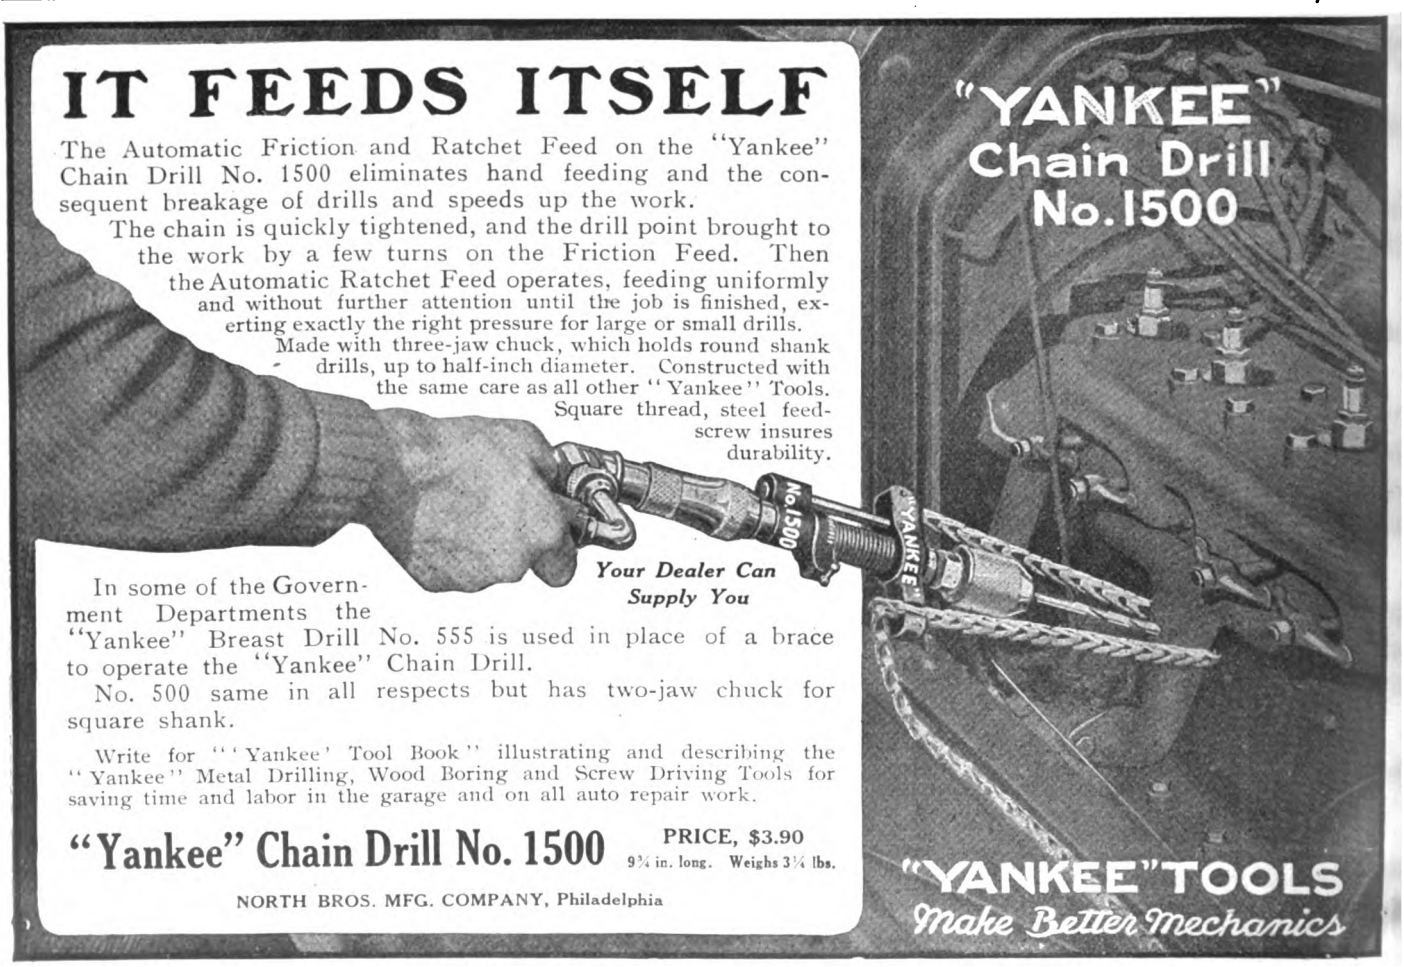
Proves our faith in their ability to make good in the severest service and warrants your recommending them unreservedly to your best customers.

There is a Master Calorite Spark Plug for every variety of service—
And the retail price is amply justified by their quality and ability for service—

$1.00 and $1.25 Retail—Depending Upon the Size

Let us send you full particulars on our proposition to the trade. You will find it most attractive.

MASTER CALORITE SPARK PLUGS
Made in U. S. A. and guaranteed by



HARTFORD MACHINE SCREW CO., 514 Capitol Ave., Hartford, Conn.

IT FEEDS ITSELF

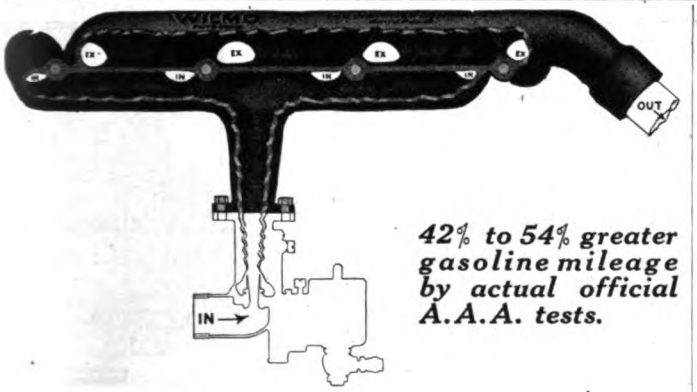
The Automatic Friction and Ratchet Feed on the "Yankee" Chain Drill No. 1500 eliminates hand feeding and the consequent breakage of drills and speeds up the work.

The chain is quickly tightened, and the drill point brought to the work by a few turns on the Friction Feed. Then the Automatic Ratchet Feed operates, feeding uniformly and without further attention until the job is finished, exerting exactly the right pressure for large or small drills.

Made with three-jaw chuck, which holds round shank drills, up to half-inch diameter. Constructed with the same care as all other "Yankee" Tools. Square thread, steel feed-screw insures durability.

Your Dealer Can Supply You

In some of the Government Departments the "Yankee" Breast Drill No. 555 is used in place of a brace to operate the "Yankee" Chain Drill.



No. 500 same in all respects but has two-jaw chuck for square shank.

Write for "'Yankee' Tool Book" illustrating and describing the "Yankee" Metal Drilling, Wood Boring and Screw Driving Tools for saving time and labor in the garage and on all auto repair work.

"Yankee" Chain Drill No. 1500 PRICE, $3.90
9¾ in. long. Weighs 3¼ lbs.

"NORMA" BALL BEARINGS

(Patented)

A trouble-proof car may be an ideal impossible to be realized. It can be approached, however, if every care is exercised to make every detail that enters into the construction and equipment of that car as nearly trouble-proof as possible. This emphasizes the important part that so-called minor details play in the performance of any car. Manufacturers of high-grade magnetos and lighting generators have found by experience that "NORMA" Bearings give them dependable bearing service—and they have standardized on "NORMA" Bearings. Makers of cars of the better class have learned by experience that the electrical accessories that give them the most dependable service have "NORMA" Bearings—and they have standardized on these magnetos and lighting generators.

Be *Sure*—See That Your Electrical Accessories Are "NORMA" Equipped

This Better Battery Means Better Business

USL STORAGE BATTERIES

U.S. LIGHT & HEAT CORPORATION

Here is a battery for which you won't have to apologize to your trade—the USL Starter Battery with Machine-Pasted Plates.

Automobile manufacturers are using more of them than ever before. Thousands of USL Battery owners naturally want to do business with USL dealers. So, if you are looking ahead, it will pay you to line up with the other live ones now making money with USL Batteries.

USL power and durability comes from the exclusive Machine-Pasted Plates. These plates are denser and tougher and are built to resist erosion longer than most battery plates.

USL Batteries in sizes for all cars are sold on a 15 Months' Guaranteed Adjustment Plan which practically amounts to battery insurance at a moderate cost.

We have a profitable proposition to make regarding Service Stations and dealers in towns where we are not represented.

If there is no USL agency in your town, write us for our proposition.

Motorists Make their own Tire Repairs!

Thousands of motorists who thought they could never repair a tire are now using the Shaler Vul-Kit. They find it easy to mend tubes and casings with this wonderful vulcanizer. They carry it right with them in their tool box and they're always ready for any blow-out or puncture, no matter how far out in the country it happens. With a Shaler Vul-Kit, you can seal the small cuts in time—before sand, dirt and moisture have been pounded into them to rot the fabric and ruin the tire.

SHALER

Vul-Kit For Tubes and Casings **$3.50**

Simple to use. Automatic heat control. No need to watch or regulate it. No chance to overcure or undercure the tire. No exposed blaze or liquid fuel to spill. Seals the cut in the tire with new rubber, protecting the fabric and making the damaged part like new.

Dealers—Write! Besides the Vul-Kit shown here there are other models of Shaler Vulcanizers for Motorists and Garages from $1.50 up, as well as complete plants for public repair shops. Write on your letterhead for our new catalog.

HOLDFORD BRAKES
SAFETY FIRST

PRACTICAL

POSITIVE

ASSURES YOUR SAFETY

HOLDFORD BRAKES are high-grade external contracting brakes for Ford cars which can be easily and quickly installed to act from the hand lever as emergency brakes, or from the foot pedal as service brakes. Designed in accordance with the best engineering practice; the band and brace are of steel, the toggle crank and bracket are dropped forgings and the lining J-M non-burn. Do not drag when released, no readjustment for wear is necessary and oiling is easy.

HOLDFORD BRAKES save wear and tear and will be attached by the wise owner on his pleasure car, delivery car or truck. They will positively stop a Ford with locked wheels on *any grade, at any speed, with any load.* Not necessary to remove old brakes.

When Ordering State Whether for Hand or Foot.

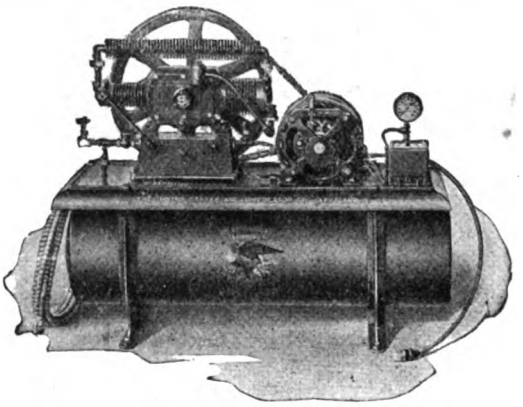
TWO-STAGE AIR U.S. AIR COMPRESSORS

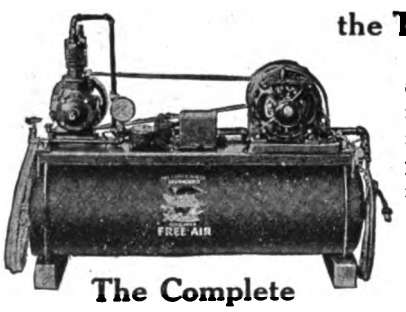
The Most Complete Line

of High Grade



Air Compressors

COMPRISING 13 different sizes and combinations, in both two-stage and single-stage types, the United States line of air compressors affords the widest range to select from and assures absolute satisfaction as regards capacity, service and price.



The U. S. Two-Stage Compressors comprise without question the most highly improved and refined line in existence, a statement which is amply proved by their exceptional performance in service and the reception given them wherever introduced. A majority of the best garages now contain this equipment and it has been adopted as standard by several companies of national prominence.

The Single-Stage line represents the highest developments in this type. They are built according to the most approved practice to maintain the same high standards embodied in our two-stage line.

Every prospective purchaser of an air compressor should have our complete catalog. Write today or send the attached coupon.

H-34 De Luxe—Automatic Unit—Leader of the Two-Stage Line

The Complete Automatic Unit of the Single-Stage Line

Adopted as Standard by Companies of International prominence.

A Look of Fresh Up-To-Dateness

Gordon Seat Covers give a look of fresh up-to-dateness that is most attractive in a motor car.

All the accumulated dinginess of travel disappears and the cushions actually seem to smile. More and more motorists are coming to appreciate this added elegance of Gordon Covers.

They fit smoothly; are cooler in summer than leather cushions and warmer in winter. Besides, they save wear on upholstery and protect motor coats from soiling. Can easily be kept fresh and clean with soap and a brush.

GORDON Seat Covers TAILORED TO FIT

are inexpensive. As low as $7.15 for Ford touring cars. Other cars in proportion. They are "tailored to fit" every American-made motor car and model. Twenty-four distinctive fabrics are used in exclusive Gordon patterns—browns, grays and tans. Weaves are especially firm and close to insure wear.

Gordon Easy On Tire Covers Are Tire Insurance

Thoroughly well made of long-wearing fabric. Give just the protection from sun and weather necessary to insure full mileage from every tire you carry. It's good business to save tires; therefore protect yours with Gordon Easy On Covers.

Dealers—Cash In On Gordon Reputation

Gordon Seat Covers have won a permanent place for themselves in the estimation of motorists. The saving, by their use, on motor clothes alone, is an item of great importance; and the further fact that they protect upholstery and add to the resale value of a car makes their use a real economy. Motorists are learning this, and also the fact that a Gordon-dressed car is a better looking car than one with bare cushions.

All these facts point clearly a way to a larger accessory business and more substantial profits.

We would like to tell you more about the Gordon line and the opportunity it offers. Write us!

The J. P. Gordon Company

REFLEX SPARK PLUGS

Reflex spark plugs are *dealer-sold*—they are *bought* by the motorist who is looking for a better plug than he usually gets with his car. Therefore Reflex plugs have to depend for their sales on *their worth to the motorist* and it is the repeat orders that account for the tremendously increased volume of sales.

Of course there are reasons—for instance, Chromite porcelain, the most durable insulating ever discovered, resists the most intense heat and eliminates the possibility of short-circuiting; the scientifically correct design assures a spark that will not only start the engine but "keep the car on the go" long after the ordinary, price-appeal plug would have been replaced. There is a model to suit every make of car and the unvarying excellence of workmanship assures the motorist of getting Reflex plugs that are all equally good.

SELLING REFLEX PLUGS is not only profitable but easy—send for our dealers' proposition and a sample plug for your own car—tell us the make.

BAILEY BALL THRUST

Replaces Thrust Washers at Left (Gear) side of

FORD and CHEVROLET 490 DIFFERENTIAL

Here is the real answer to that far reaching cry for an efficient remedy of axle difficulties, noisy or broken gears—the answer to that need for a bearing that will replace the old style, inefficient thrust washers used as standard equipment in Ford and Chevrolet 490 differentials, that through their sliding contact wear thin in no time, and cause drive gears to shift away from the drive pinion, creating havoc with the gears.

THIS NEWEST INVENTION

Of a master engineer, the BAILEY BALL THRUST BEARING is an exact replacement made to fit to the thousandth part of an inch, and will positively keep gears in proper mesh, make them run quietly and last indefinitely. They will not wear thin.

DEALERS GARAGEMEN REPAIRMEN

All over the United States and Canada, wise men are stocking this bearing. Go after this replacement business. It is a source of profit for you and yours providing you can supply the customer's needs at a moment's notice. It will not do to order at the last minute, because the car-owner insists upon immediate service, and you must be prepared.

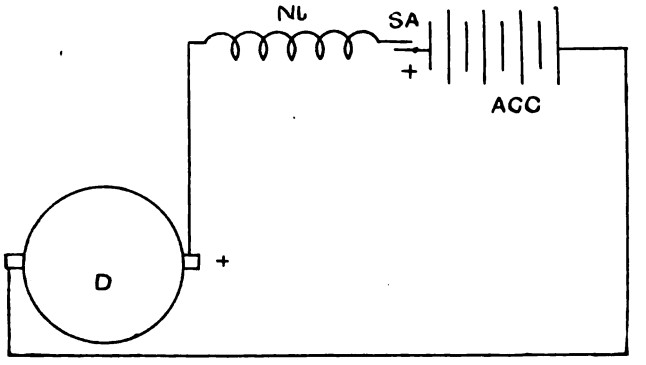
MORE BATTERY FACTS.

The Rheostat, Resistance, Heat, the Aid of Auxiliary Brushes, Etc.

BY SYDNEY F. WALKER, M. E.

No. 4.

The rheostat is an apparatus that is very much employed in electricity generating stations, to vary the current passing in the field magnet coils of both



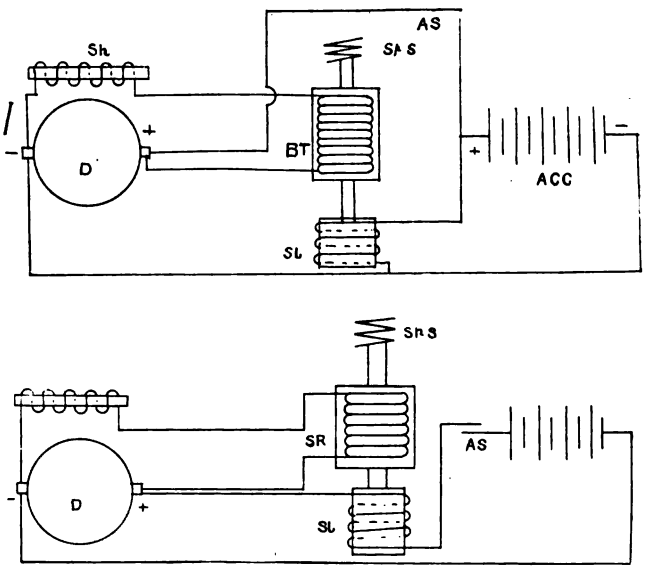


Fig. 15.—Diagram showing the method employed by the Lithanode Company of London, in which a nickel wire absorbs the increased pressure due to the increased speed.

continuous current and alternating current dynamos; it is a very convenient apparatus indeed, and gives the engineer in charge very full control over his machines, and the pressure they furnish; but rheostats made for electricity generating stations can be constructed on very much more generous lines than is possible in a motor car, and their contacts are under constant supervision. The rheostat itself consists usually of a length of wire, drawn from a metal whose coefficient of increase of resistance, with increase of temperature, is very small indeed, almost negligible, and it is constructed so that the heat liberated in the resistance wire by the passage of the current is able to get away freely. The dimensions are such that the heat liberated is not great. The quantity of resistance thrown into the field magnet coil circuit is varied by moving a contact bar over successive points in the wire itself, or over metal blocks attached to points in the wire.

The great danger with contact arrangements of this kind is the possibility of sparks passing between the contact bar and the metal block it is leaving, or the point of the resistance wire it was leaving, and of sparks passing between adjacent contact blocks. For electricity generating stations, all of this has been carefully worked out, so that these dangers are well guarded against; but to ensure doing so requires space, and space is not available usually in the motor car. In the motor car also the variable resistance has to be thrown in and out, its amount varied automatically, while in the electricity generating station it is usually done by hand, and this introduces another considerable difficulty into the problem. Automatic apparatus have been worked out during the last twenty years for starting motors from a distance, for starting dynamos that charge accumulators, when the pressure at the accumulator falls below a certain figure; and in all of these a contact arm is made to move over a number of contact blocks, the contact arm being operated by an electro magnet. The majority of these work very well, but again there is plenty of space, and the contact bar and the stationary contacts are usually in sight, so that they can be examined periodically. The contact arrangement of a motor car can of course, and ought to be examined periodically, but the conditions are very unfavorable for using a variable resistance. The most favorable case the writer has seen is that in which the property of iron wire is employed to govern the current flowing through the shunt wire field coils. It is not employed directly; it does not act directly as the resistance in the shunt field coil circuit, but the effect is the same; the current flowing in the field coils is reduced owing to the resistance of the iron wire in a portion of the circuit having increased, this again being due to the attempt of the dynamo to furnish a larger current in the outer circuit. It is shown in Fig. 16 as employed. Iron wire and nickel wire have peculiar properties that have been found very useful in con-

Figs. 16 and 16A—Diagram showing the method suggested by the writer for using a number of carbon pellets in a brass tube, to vary the resistance of the shunt field magnet circuit, by varying the pressure between the pellets. Normally the pellets are kept closely pressed together by the spiral spring shown above the tube; when the pressure rises above a certain figure, the solenoid electro magnet below releases the pressure by pulling the plunger downwards. The arrangement is shown with the operating electro magnet excited by a shunt coil, and a series coil.

nection with electrical apparatus. Iron and nickel have each a critical temperature, at which any increase of temperature gives a large increase of the resistance offered by the wire, while any decrease

Digitized by Google

of temperature gives a comparatively large decrease of resistance.

It will be remembered that when a current flows through a wire, the passage of the current causes heat to be liberated in the wire, raising its temperature; with the iron and nickel wire employed, the current passing is arranged to raise their temperature to the critical figure under normal conditions; that is to say, when the pressure is at the proper working figure; any attempted increase of pressure, by causing a rise in current strength, causes an increase in the temperature, and a large increase in resistance, sufficient to reduce the pressure to the proper figure. Nickel wire, so far as the writer is aware, is not used for controlling the current flowing in the shunt field coils, but for controlling it in the main circuit leading to the accumulator; a length of nickel wire of a sufficient size to carry the full charging current to the accumulators, and to be raised to the critical temperature when that current is flowing, is placed in the main circuit. It is of sufficient length to choke back any attempted increase of current due to a rise of pressure. With this method, shown in Fig. 15, the use of the nickel wire in the

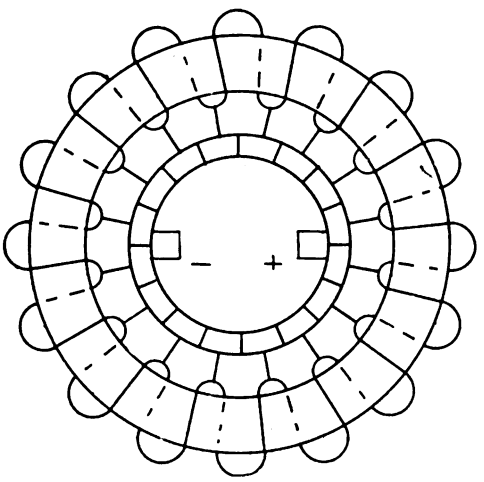

Fig 17—Diagrammatic sketch showing the arrangement of the coils of wire on an armature, and their connections to the segments of the commutator, also the brushes bearing upon the commutator.

main circuit, the pressure at the brushes is allowed to increase, but the increased pressure is absorbed by the increased resistance of the nickel wire, in accordance with the law stated in an earlier part of the article.

When finely divided carbon is compressed, its electrical resistance may be reduced to a very small figure, depending upon the amount of compression; when the compression is removed, and the grains of carbon can move more or less freely, the electrical resistance offered increases very rapidly. Small pellets of carbon might be employed, held in a tube, and arranged to be squeezed together or released, according to the requirements of the service. For the low pressures employed in motor car lighting, the carbon pellets might be held in a brass tube, greased with kerosene oil on the inside, without any appreciable leakage of current. Figs. 16 and 16-A show the writer's idea of an arrangement for using a number of carbon pellets, held in a brass tube, to act as a variable resistance in the circuit of the shunt field magnet coils. As will be seen, the carbon pellets are inserted in the circuit of the field coils, and they are kept pressed close together, either by a spiral spring, acting upon a plunger which forces them together from below, or a weight from above. The plunger which forces them to-

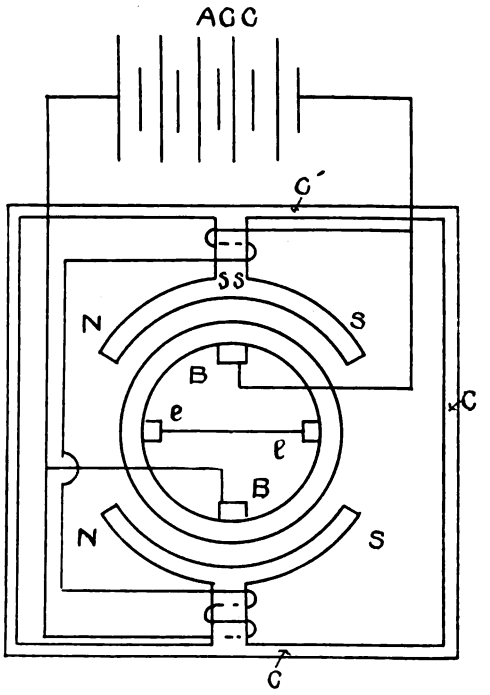

Fig. 18—Diagram showing Mather & Platt's arrangement of a self-regulating dynamo.

gether, in either case, is mechanically connected to the iron core of a solenoid electro magnet, whose coils are of very fine wire and are connected across the brushes; they may be in the same circuit as the fine wire coils of the automatic cut-in-and-cut-out. The spiral spring would be sufficiently strong to keep the carbon pellets very firmly pressed together, under ordinary running conditions, in spite of the pull of the solenoid electro magnet upon its iron core; and the solenoid would not be able to overcome the tension of the spiral spring, until the time arrived when it was required to insert resistance in the shunt field coil circuit; that is to say, when the pressure of the dynamo reached a certain figure, say 2.5 or 2.6 volts. On the arrival

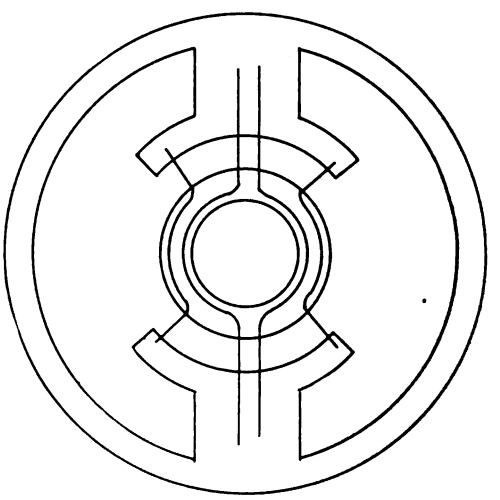

Fig. 19—Diagram showing the lines of force due to the fiel magnets of a dynamo.

of that pressure, the pull of the solenoid would over come the spiral spring, and the plunger would b pulled downwards, allowing the carbon pellets t

Digitized by Google

nove more or less freely, and increasing the resistance offered by them. With apparatus of this kind, in which carbon blocks, finely divided carbon or carbon pellets are alternately pressed close together, and allowed to move by the relief of the pressure, there is often a diifficulty in obtaining the requisite movement to give the increased resistance; the writer's view is that the vibration of the car would give this movement. The solenoid electro magnet could be wound with a thick wire, included in the main circuit, between the dynamo and the accumulator, if preferred, as shown in Fig. 16-A; it would then come into operation when the charging current exceeded a certain figure, and would be increased as the charging current tried to increase.

The Aid of Auxiliary Brushes.

There are at least three methods employed for maintaining the pressure at the dynamo brushes at the figure required at the moment, by the aid of additional brushes. In order to understand them, it will be as well to consider the arrangement of the coils of the armature of a dynamo. They are shown diagrammatically in Fig. 17. The coils represent those on the armature; the divided up cylinder represents the commutator; and the blocks represent the

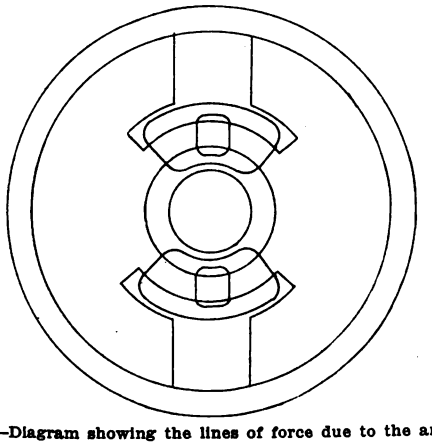

Fig. 20—Diagram showing the lines of force due to the armature current.

brushes. For simplicity, a two-pole dynamo is taken, but all the reasoning that follows applies equally to a four-pole machine; also the arrangement of the coils is given in the very simplest form. There are several methods of winding the coils on the armatures, designed to give greater efficiency to the machine, and for convenience in construction; the differences in the methods employed do not affect the problem involved in the use of auxiliary brushes.

When a dynamo is generating current; with a two-pole machine two distinct currents are flowing through the armature; the armature coils are divided into two halves by the brushes, and the currents that are being generated flow through the two halves, from the negative to the positive brush. Consequently the pressure existing between the two brushes is, say 12 volts with a 12-volt set, or 6 volts with a 6-volt set; the even figures are taken for convenience in calculation; there is a continual fall of pressure along each half of the coils of the armature, from the positive to the negative brush. Suppose, for convenience in calculating, there are 24 coils, counting all round the armature, 12 on each side; there will be a difference of pressure of 1 volt between the two ends of each coil. The adjacent ends of adjacent coils are connected to a segment of the commutator, as shown in Fig. 17, so that there will

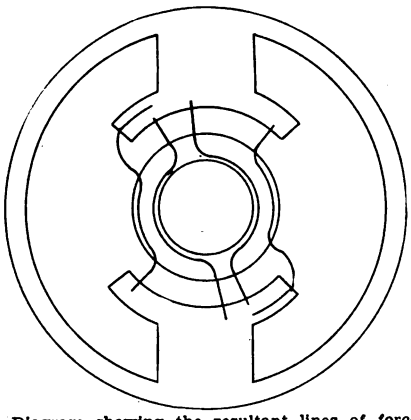

Fig. 21—Diagram showing the resultant lines of force, due to the operation of the two magnetic pressures.

be a difference of pressure of 1 volt between each segment of the commutator, and at a point say half way between the brushes on either side there will be a difference of pressure equal to half the total pressure between the brushes.

To understand the working of these systems, it will be necessary to go a little deeper into the operation of a dynamo machine. Electric current and pressure are produced by the passage of the coils of wire on the armature, through the magnetic field created by the field magnets in the cylindrical polar space in which the armature revolves; electrical engineers are accustomed to say that the armature conductors, the copper wires on the armatures, cut the lines of force passing into the armature, and across the air space between the pole pieces and the armature core. But, immediately the armature conductors have currents flowing through them, those currents create their own magnetic pressure, so that there are two magnetic pressures acting within the polar space in which the armature revolves. The magnetic pressure created by the currents flowing in the armature coils is not directly opposed to that created by the field magnet coils; a resultant magnetic pressure is produced, very much on the lines of the resultant force in mechanics, where the old rule of the parallelogram of forces comes in.

Fig. 19 shows the lines of force due to the field

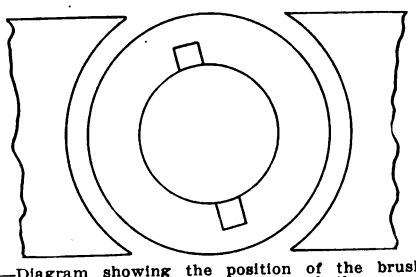

Fig. 22—Diagram showing the position of the brushes of a generator, when no current is passing through the armature; this is what would take place, if it were possible for no current to pass through the armature, when the machine is furnishing current. It is very nearly correct for a shunt wound dynamo, with no current in the outer circuit.

magnet coils; Fig. 20, those due to the armature currents, supposing there were no field magnet currents; and Fig. 21 the resultant lines of force. Elec-

trical engineers are accustomed to draw the direction of the lines of force in the way shown in these figures; and approximately to indicate the number of lines by the density of the lines in the drawing. The direction of the lines of force, as shown on the drawing, is that which a small needle magnet would take, if it was free to move, and it was placed anywhere within the magnetic field. In the ordinary continuous current dynamo, the only effect of the presence of the magnetic pressure created by the armature currents, is an alteration of the position of the brushes. If there were no magnetic pressure

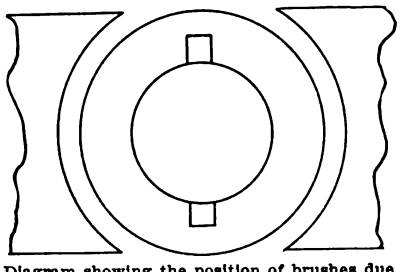

Fig. 23—Diagram showing the position of brushes due to the flow of the armature current; the position is slightly exaggerated to make the operation clear.

due to the currents in the armature coils, the brushes of a two-pole dynamo would be placed at opposite ends of the diameter, lying between the pole pieces, as shown in Fig. 22. Owing to the magnetic pressure created by the armature current, the brushes are thrown slightly forward in the direction of rotation, in the case of a generator, as shown in Fig. 23; and slightly backward in the case of a motor.

(To be Continued.)

AMONG NEW JERSEY GARAGES.

Air Pumps and Tanks and the Care Necessary for Buying An Automobile Truck.

BY JAMES F. HOBART, M. E.

There seems to be a growing disposition among garages and repair shops to dispense with the fixed compressed air tank and its piping and to use instead a small air pump, electrically or gas engine driven, which may be readily taken from place to place and attached directly to the tire to be inflated.

A little while ago, there was described in these columns, an air-tank on wheels, truck fashion, which was filled with air at a fixed pump, then the tank was trundled around the shop, out of doors, or anywhere in fact, where a tire needed air. In this way, all the expense and losses pertaining to pipe lines with possibly leaky valves and fittings were obviated.

But the above described arrangement still kept the tank, which, as usually provided, seems to develop leaks. Recently the writer saw an air pump which seemed to fill the bill from every point of view. The apparatus consisted of a little three-wheel cast iron frame to which were fastened three wheels or casters, each about 4 inches in diameter, thus enabling the truck to be readily pushed in any direction at will.

Upon the little truck was located a combined gas engine and air compressor, both elements being attached to the same crank case and the pistons being opposed to each other. The gas, or working cylinder was enclosed by a water jacket which carried a vertical addition about 10 inches deep, forming the water reservoir or tank, directly above the working cylinder, rendering pipes, radiator and connections unnecessary. The top of the water jacket tank was open so the quantity of water therein could be seen at any minute.

The little compressor cylinder, as stated, opposite the power cylinder, was air-cooled, being surrounded by the usual radiating rings for that purpose. Right on top of the air-tight cast-iron crank case was a small vertical cylinder or can, evidently made of pressed steel, in which the gasoline supply was contained. The capacity of this tank was evidently about one quart.

Adjacent to the air compressing cylinder, and very close to it was another closed steel vessel or can, about as large as the gasoline tank. Air direct from the compressing cylinder was led into this last named vessel, the pipe entering at the top and evidently passing down inside nearly to the bottom at which level there was located a drip pipe and valve.

The air pipe to which the filling tube was attached, was taken from the side near the top of the "settling tank", as the little vessel above described may be termed, the object being to catch and hold as much as possible of the water which always makes itself present when air is compressed. The water being caught in the little separator, can be drawn off through the drain pipe and valve when too much of the liquid has collected. The blowing off is performed very quickly by opening the drain valve while the compressor is working, the moisture being driven out in a hurry by the air pressure.

A balance wheel about 11 inches in diameter rides on the end of the crank shaft which projects from the crank case. A starting handle is attached to the balance wheel in such a manner that it may be used to turn the wheel while starting the engine, but as soon as the wheel revolves under its engine power the handle turns upon a pivot and disappears inside of the wheel-rim where a recess has been provided to receive the handle.

A battery box is also mounted upon the little cast iron truck and a switch upon the side of the box is so located that it may be operated by hand or by foot when it is desired to stop the engine and compressor. This little machine works so nicely that it should be adopted by many shops and garages. It is easily pushed to a wheel, the switch thrown and a turn with one hand starts the engine almost instantly, then the air tube may be attached to a tire and a 35x4 inch tube pumped up in a very short time—in almost as little time as is required to attach the tube from an air cylinder and open the necessary valves.

I tried to discover the "pedigree" of this little air compressor but the folks of the garage could tell nothing save that they "bought it for five dollars from some man who brought it around." No name could be found on the machine but perhaps some automobile worker will recognize the machine and advise the Editor of the Automobile Dealer and Repairer where the machine is made or where it may be procured. The machine is worthy of extensive use in garages and automobile repair shops.

Electrically operated air-pumps are to be frequently found in Newark auto shops. These pumps

Digitized by Google

are built much upon the same principle as noted for the gas-engine driven affair but they may necessarily be made much smaller and more compact. There is only one disadvantage in connection with the electrically operated air pump without receiver or storage tank, and that disadvantage is the cord or wire with which the little machine is connected to the source of electricity.

There is no getting away from the fact that an electric connection under foot all the time is most awfully in the way, and with the necessarily long connection required for the electric air pump, there is frequent trouble from breaking of the connection wires, from their tangling up and from the time necessarily lost in keeping the wires or cord clear of the garage tools, machinery and vehicles.

A considerable amount of this annoyance might be avoided by fitting the portable electric air pump with an attachment plug and then arranging sockets at frequent intervals around the premises so that the pump could be connected almost anywhere and everywhere, thus doing away altogether with the long cord necessarily under foot.

But for ease of connection and operation, the writer has never seen anything which compares with the little gasoline-driven air pump described above. It surely was on the job every minute and as it was in a repair garage where cars are coming and going every minute of the day and night, the machine surely did a good deal of work. And never yet, during any of my visits, have I found the little machine out of order or fail to respond instantly to a throw of its battery switch and a turn of the balance wheel.

Buying An Automobile Truck.

The writer has recently watched with much interest the acquiring of an auto truck by a small concern engaged in a combined express, grocery and green-grocery business which made bi-weekly trips between Newark, N. J., and New York, and on all other days of the week, Sundays excepted, was delivering goods to local patrons.

The horse, an old-timer from the fire department, which had been released by the auto-fire truck, was a good animal, strong and willing, but necessarily a bit slow when loads of a ton were to be hauled around Newark all day and loads of two tons or two tons and a half hauled from New York twice a week over the twelve miles to Newark.

The firm of dealers got an idea that a motor truck would enable them to increase their business and began to look around for a second-hand automobile which they could have changed over into a commercial vehicle. They looked at several Fords, but wisely decided that, although a Ford made a very nice delivery wagon for light local work, that it was not heavy enough for 12-mile trips with two tons or more of goods on board.

Next, they looked over a Studebaker car of 1914 and liked the looks of its rugged construction very well. The writer was asked to go along and look the car over with a view to its being transformed into a delivery vehicle. Apparently the machine was in pretty good condition, the paint was not scratched and the upholstery was whole, not torn or badly scratched, thus showing that either the car had been pretty well taken care of or it had been newly "done-over" at some very recent date.

The engine was declared by the dealer to be "in good working condition", but there should be a clause in the license of each and every automobile dealer defining exactly what was implied when an engine was guaranteed to be in "good working condition". That clause would cut out some of the "horse-jockey gospel" of "used" gas wagons. Anyway, the "good working condition" went in at one ear and out at the other so quickly as to certainly justify a statement by the dealer that "there was nothing inside the head to stop it!" The steering gear was tested out for wear and lost motion by placing a man at the wheel to move the wheel gently back and forth varyingly increasing distances, beginning with a very small arc which was increased until, with a hand on either forward wheel, they were felt to move slightly as the steering wheel was turned.

In this way, the amount of lost motion in the steering connections was quickly determined and found to be about a four-inch movement of the rim of steering wheel. The wheel movement was repeated with the writer's hands upon the front part of each forward wheel just level with the axle. A slow movement of the steering wheel showed that one front wheel began to turn a trifle before the other one started, more evidence of wear in the steering gear and knuckles.

A close survey of the wheels from front and from rear showed that the left front wheel had more "gather" than its mate. The garage man of course could not be induced to see it, therefore a carpenter's square was procured and placed against a strip of straight board, one end of which rested on the floor, the other end against the rim of the suspected wheel at the top. The strip of board was brought against the square until exactly perpendicular, then with a scale, the distance was measured perpendicular to the strip of board to the wheel rim, both top and bottom. It was found that the distance at the bottom was 1 1/16 inch greater than at the top of the wheel, thus showing conclusively that something about the axle or knuckle was worn or "sprung". A test of the other forward wheel showed but 1/16 inch more distance at bottom than at the top, this wheel being practically vertical. By this test, even the garage man was forced to acknowledge that something about the front wheel was "leery." Both ends of the front axles were then jacked up at the same time and a vigorous shaking of each wheel showed conclusively that a good bit of work must needs be done on the axles and knuckles before the car would be fit to be rated as in "first class mechanical condition."

The front wheels were released and the rear ones jacked up, both at the same time and the transmission thrown into gear. Then, with a man at one of the rear wheels, the writer at the other wheel was able by various movements and shakings of his rear wheel, to form a pretty good idea of the amount of lost motion in the transmission, and that there was more than a-plenty, was quickly in evidence.

The jacks were removed from under the rear axles, and solid blockings put in place of the jacks and the engine started with the wheels free from the floor. A little squirt of gasoline in each priming cup, and away went the engine at the very first pull of the starting crank. This must have been the reason for the garage man's statement that the engine was

Digitized by Google

in "excellent working condition". If noise means capacity for work—which it doesn't—there certainly would be ample grounds for his assertion.

Did you ever run an automobile with both rear wheels held free from the floor? Well, if you haven't, and if you want to find out just how much looseness there is in the engine, try it. It seems as though each and every bit of play or lost motion was accentuated and made more prominent by the "backlash" of the many moving parts. The scheme worked well in this instance and showed the writer that there was a whole lot of work to be done on the engine and the transmission before the apparatus was fit for a truck foundation.

The running of the engine at various speeds with the clutch open, also told a story of its own about looseness and wear of engine parts. Don't let the garage man fool you during this test. Better pull him out of the machine and take the wheel yourself, then you can run the engine steadily at various rates of speed and note the rattle at the various revolutions. The garage man will probably be "on the job" and during this test, he will keep the gas lever moving, slowing the engine down, then quickly speeding it up with a rush and with a clatter of the exhaust in a manner which prevents almost entirely a careful study of engine noises at various speeds. Just pull him out of the car and make the engine test in your own way and you will be able to tell far more about the condition of the engine than if the garage man was allowed to do this "monkey business" at the throttle.

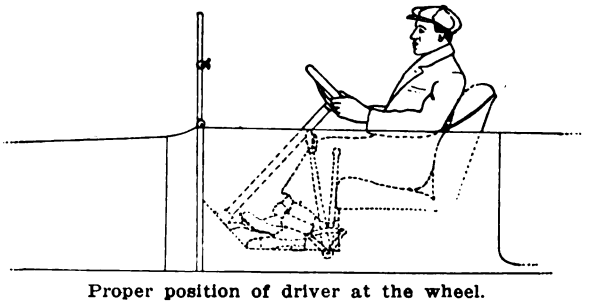
The asking price of this Studebaker car was $250. The writer advised the prospective purchaser that he would have to spend at least $50 for engine repairs and $50 more for axle, knuckle and transmission overhauling, including the steering gear. It was also shown that at least $200 must be expended for a truck body and top and for fitting same to the old machine. This totals $300, and added to the asking price of the old car, amounts to $550 for the truck when complete.

For this reason, the would-be purchaser was advised that he could not afford to pay more than $150 for the old car with a view of converting it into a commercial vehicle. He also asked the writer to look over a "used" jitney which had been running around town for a year and had been discarded for a larger vehicle.

The writer very promptly "sat down" upon the proposition to purchase the old jitney and use it for a truck by changing the rear door. Being pressed for reasons, the purchaser to be was told that a light machine which had been converted into a "jitney" would in all probability be found badly worn and pretty well racked to pieces. The jitney must stop at about every street corner it comes to, and the strains of stopping and of starting again almost continually are so great the light mechanisms are very quickly worn out by the hard service and that it very seldom will pay to purchase for improvement or for permanent use, any automobile which has been used in jitney service.

Finally the purchaser to be was advised to buy a new commercial truck and be sure then of getting his money's worth. But, should it be beyond his present means to obtain a new vehicle, to purchase outright a used motor truck and not to bother with the changing over of a pleasure car into a commercial vehicle.

He was also informed that used motor trucks could be obtained for almost any sum from $50 up—the writer actually finding one for sale at that figure, the advertisement reading:—"Two-cylinder Buick delivery wagon; closed body in running condition, $50." I didn't advise the parties who wanted a truck to invest in this vehicle, but it shows what can be had in the truck line.



The writer did advise, however, that the purchase of any vehicle which might be selected, should be based upon the report of a disinterested repair man who would be willing to contract to make the repairs he might specify after a thorough examination, the engine being dismantled sufficiently for that purpose, but to always remember that auto trucks which are good for much are seldom sold until they are badly worn out, except occasionally when replaced by larger vehicles. Therefore, when negotiating the purchase of a used motor truck, accept solely upon the exact physical condition of the mechanism as revealed by actual inspection.

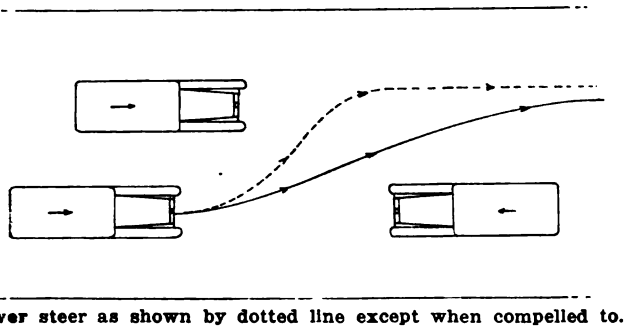
If the owner will not permit a dismantling examination, or will not give a guarantee, then it will not be for your interest to bother with the used car and you had best save your time and look elsewhere. It is no more than right that the man who wore out the vehicle should pay therefor, as the wearing out has or should have netted him considerable profit and he should be willing to sell the used car at its actual value to the purchaser. This course will prevent "scalping" of used cars by the unscrupulous dealer—or rather the "scalping" of the purchaser who does not see for himself exactly what he is to obtain.

STEERING THE CAR.

How to Do So Easily and to Avoid Liability of Trouble.

The question of steering a car is one which embraces a great number of small points. In the first place, if one is buying a new car it should be a primary consideration that the driving position is

Proper position of driver at the wheel.



a suitable one. The position assumed has to be a compromise between what one may term the most efficient one and the most comfortable one, and where there is any question of doubt precedence should be given to efficiency.

In an ordinary touring car one should neither have to lean forward nor should one loll in a too backward position, but the seat should be so arranged as regards height and slope that, while one has a good support for the back on the rear of the seat, the

Digitized by Google

feet are in a "powerful" position to control the pedals. At the same time, the reach to the side brake lever must not be too great.

A choice of two methods of pedal-control movement may be offered, according to the available length in the driver's seat and the pressure necessary comfortably to operate the pedals. If the clutch pedal is stiff and the reach is fairly long, then the action comes more from the upper part of the leg, and suitable purchase is obtained with the small of the back in order to get sufficient pressure on the brake pedal, or to hold the clutch out for any length of time. If the pedal-control is easy and the leg-

Never steer as shown by dotted line except when compelled to.

room is shorter, then the ankle and lower portions of the leg are the chief controlling factors.

Then, again, one should so sit that the line of vision is quite clear ahead, and it is certainly preferable, if one has much traffic driving to do, to be able to see the tips of the wings, although the present fashion in coachwork often renders this difficult or impossible.

The steering wheel should also be in a handy position, and, while not too close to the body, should not be so far away as to make it necessary unduly to hang the hands out at a distance. Yet again, if one habitually drives by the accelerator pedal, as the majority of drivers do, and that movement is not thoroughly comfortable, the pedal should be altered, if necessary, so as to be in a position where the right foot is more or less at rest. If a long drive tends to give one cramp in the ball of the foot it shows that the requisite depression of the accelerator pedal is either too great or else at a wrong angle to the ankle, and a little longer pedal will probably be found an improvement.

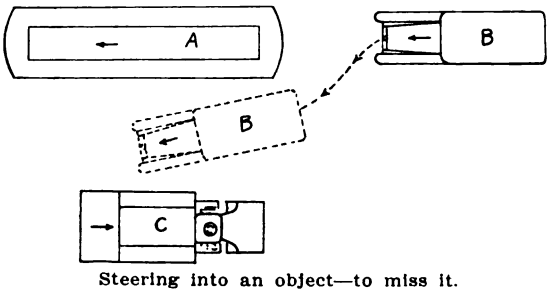
The driver should also endeavor to cultivate a comfortable appearance at the wheel, which is not merely a matter of looks, as in addition to appearing at home with his work—and therefore calm and collected as a good driver should be—it is an attitude likely to encourage the actual obtaining of such a desirable state of affairs.

Many car drivers have a nervous appearance, which gives a bad impression from the mere point of view of looks and does not promise well for actual fact. The capable driver usually has the appearance of being as much at home at the seat of the car which he is driving as one would expect to find him when comfortably ensconced in an armchair by his own fireside.

With Regard to Steering.

With regard to the actual question of steering, the best general rule that can be laid down is never to steer suddenly except when such action is absolutely necessary.

For example, having followed a cart which it is desired to overtake, do not come up to within 10 yards of it and then suddenly swing out to the other side of the road to pass it. It is far preferable gradually to work one's way to a position on the off-side of the cart, starting, say, when 50 yards from it. Not only is it safer, enabling a more complete view of the road in front of the cart to be obtained—and obtained in good time—but it is also distinctly better both for the steering gear, the tires, and the car in general.



When the road is greasy this point is of even more importance for several reasons. In the first place, if one has not a metallic non-skid tire on one of the front wheels, a greasy road may mean a front-wheel skid (this matter is dealt with more fully in a later chapter devoted to skidding), while even if this should not occur one of the more ordinary type of skids may be caused.

How to Hold the Wheel.

This, again, is a subject in which there are many variations, and the personality of the driver must necessarily enter into the subject. For instance, when giving any hints on this subject, the size of the driver's hand and the strength of his fingers and wrist must all enter into consideration. A large number of motorists make a habit of driving a considerable proportion of their time with only one hand on the wheel, but really it is just as easy, when one is accustomed to it, to use both without any fatigue.

One is almost justified in stating that it is preferable to make a habit of using both hands for steering, as then, in case of emergency, the right hand is instantaneously ready and in a handy position to grasp the side brake, while the left hand is already on the wheel and the grip merely wants tightening a little in order to perform the work demanded from it.

If one is in the habit of using first the right hand and then the left, it may so chance that when the right is being used a sudden emergency case crops

Steering into an object—to miss it.

up, when it is necessary first of all to get the left hand to the steering wheel, and then remove the right hand to the brake lever. It may be that it only takes a fraction of a second so to do, but the value of a fraction of a second as frequently constituting the difference between having an accident and just missing one has already been shown.

Quite a good plan is to hold the steering wheel with the back of the hand upwards, the fingers going round the top of the wheel with the thumb underneath. Alternately, this grip may be reversed, though in each case the grip, although being reasonably firm and instantaneously ready to be very firm, should not, under ordinary circumstances, be too tight.

Digitized by Google

The actual place on which the hand should rest on the wheel is also of importance, and it should not be held on that portion of the wheel next to the driver's person. On the contrary, it should be more to the side of the wheel, as in this position the rotation of the wheel is caused by a direct push or pull from the arm, which is far more powerful, and quicker in action, than the lateral motion possible if the wheel is held at the bottom.

If nature has provided one with a large hand and fingers, the grip in which one of the steering arms is always between the first and the second finger is a very powerful one, and is more quick in its ability to grip and control the steering wheel than the other type. Unless, however, one has got a big hand and fingers, this grip may prove too fatiguing. It should, however, be tried, as it is undoubtedly an excellent grip when one can manage comfortably to span the steering arm.

Some Alternative Grips.

Whatever position one takes with regard to holding the steering wheel, on a long journey one wants a change. What the writer terms the tension grip is quite sound as a change for open country work, and is also quite restful. It is not so suitable for town work or for very quick manoeuvring.

The grip in question is only properly permissible when it so chances, as frequently is the case, that, while the direction of the car is straightforward, the steering wheel has an arm each side of it at right angles to the direction of progression, or, say, parallel with the dash. In this case, one places the fingers of each hand over the steering arm on the respective sides of the wheel, the fingers gripping the wheel and a slight tension being put on the arms —what one might term just a hanging tension. As each arm is now in tension to check any irregular tendencies of the steering, the change arm is quite a distinct rest for the arm, as it is not called upon now to do any compressional work. If an obstruction to the right wheel tends to throw the steering to the left, then the fingers of the right hand resist that action in tension, although if the movement should be in the opposite direction then the left hand is called into play. The grip in this case is a little lighter than in the other types previously referred to.

With regard to the sudden tightening of the grip, if a bad road obstruction is met with and the steering wheel needs strong checking, then the increased tension is found to be quite automatic and instinctive, as the steering arm on the side in question is thrust more firmly against the fingers, which automatically in the act of restraining a forward movement also increase the grip.

While bearing in mind that this grip is not advocated for traffic driving, it will be found a very restful change for ordinary touring work in the country.

Yet a fourth method of holding the wheel, which can also be used as a change, is that in which the first finger and thumb grip the steering arm from above, while the rim of the wheel is between the first and second fingers. This grip again is similar to the last-described one, and is more what one may term a checking grip than an actual steering grip, and is not recommended for town use but only for country use, where the road is fairly open and no sudden maximum movement of the wheel is at all likely to be required. Both hands may be used simultaneously, or if the driver does not find that he can conveniently train himself habitually to use both hands for steering, then for open country work it may even be safe to use the one hand.

Perhaps, however, one ought to add even another qualification to this type of grip: it should not be used either for high-speed work or on rough roads. The reason why both these latter grips are only advocated for resting purposes, and for what the writer terms check steering, is that there is only direct power over a very small arc of the steering wheel's travel. Obviously, when one has made a little more than an eighth of a revolution of the wheel in either direction further movement has to a large extent to be caused by lateral pressure from the arm which is nothing like so powerful as the direct pull or push.

Passing Other Vehicles.

As a general rule leave a fair amount of space between yourself and any other vehicle which you are passing. To be able, in case of necessity, successfully to pass some object with only an inch of clearance is a most excellent attribute to a driver's skill, but if such a proceeding is indulged in habitually then it is nothing more nor less than crass stupidity. There are all sorts of clever things which the really capable driver should be able to accomplish but which the really capable driver never does accomplish except in cases of necessity. Tight corners do occasionally occur, due either to one's own semi-recklessness or to the stupidity of some third party.

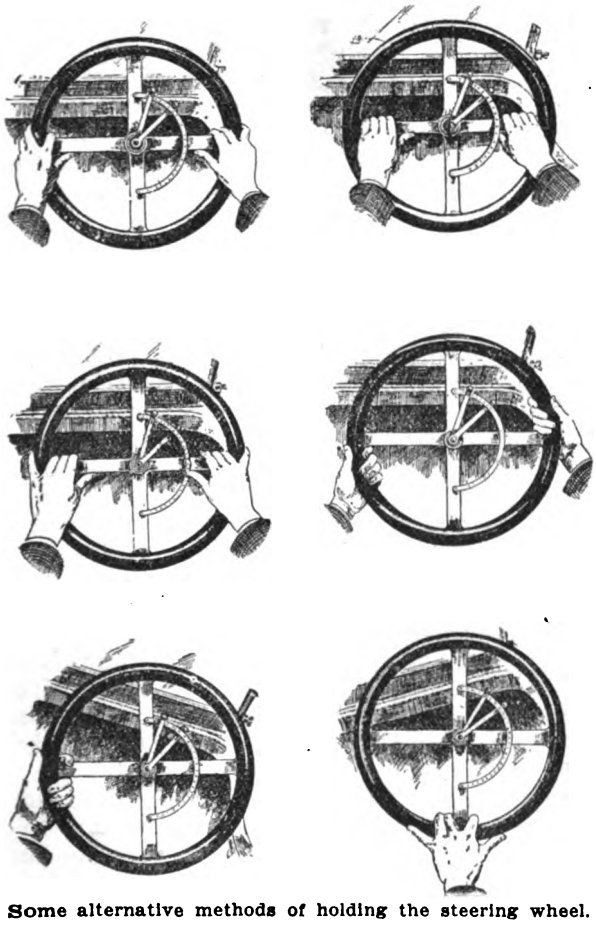
A Not Uncommon Tight Corner.

When such a thing as a "close shave," as it is usually termed colloquially, has to be encountered with regard to steering, do not endeavor to look at both sides at once. This is a fatal mistake, yet it is one which the vast majority of drivers seem to make.

If, for the sake of example, you suddenly find yourself with what you doubt to be sufficient room to pass between the wheel of a steamroller on one side and a brick wall on the other, it can serve absolutely no useful purpose to try and look at both sides of the car when making the attempt.

It will serve no useful purpose to enumerate the many occasions when, from one cause or another, one is faced with an unpleasant proposition of this kind, so we will merely consider the example quoted as a criterion of other similar situations.

Assume, then, that the brakes have failed on a hill, or that for some reason or other we see in front a road bound on the one side by a brick wall and on the other side a steamroller. It is entirely out of the question to be able to stop in time, and the only chance of safety is to pass between the two obstructions. Is there room to pass? Primarily, so far as possible, keep quite cool. That advice is easy to give, but of course we all know that the ability successfully to keep one's nerve in a case of emergency varies with the person in question.



We are assuming that it is impossible to stop, therefore do not jam the brakes on too much, as this is sure to upset the steering, and anything in the nature of a skid may render a successful passage through the narrow imaginary spot an impossibility. Apply the brakes then only so much as they do not

Digitized by Google

affect the steady direction of the car. If a pretty expert driver, they can be put on fiercely some distance away, the car straightened up again, and then the secondary application made of only such strength that it will not now affect the steering.

Do not look first at the brick wall and then at the steamroller and try and figure out whether it is possible or whether it is not. The assumed circumstances are such that one has either got to get through or have a smash-up. If there is to be a smash-up the more nearly you get to passing through, the slighter the accident is likely to be.

Take, then, the left hand object (we will assume it is the wheel of the steamroller) and steer just to miss it with your front wing and try and brace yourself to the knowledge that if the first few inches of the front wing successfully pass the wheel of the roller the rest of the car will do likewise. This fact

Some alternative methods of holding the steering wheel.

is important, as in such cases there is always an idea which rushes to the mind that although the thing has just been missed at the beginning, one is steering into it, and therefore it is necessary to steer away from it.

Do not, then, steer out through sudden alarm, because you imagine you are too close to it, but keep the eye firmly on that front wing and the steering quite steady until you are through. If there is room, then, by adopting this means you will get through. On the contrary, if, as so frequently is the case, one glances first to the right and then to the left the manoeuvre is by no means so likely to prove successful.

If in point of actual mechanical fact there is not room for the car to pass, then an accident must, of course, ensue, but the fact that you are, so to speak, in the middle of the two objects is likely to minimize the accident rather than if you hit one of them fairly full and altogether cleared the other.

For example, a somewhat inexperienced driver, or one who lost his (or her) head, might clear the wall on the left by a foot, through the powers of vision not being so capable of precise judgment on this side of the car, only to catch the mudguard against the wheel of the steamroller and also perhaps the axle cap. This would, of course, swing the car round and probably dash it into the wall.

More than one case somewhat similar to this has come under the writer's notice, where the driver has absolutely ripped off mudguards and splintered the running boards both sides of the car yet come through without any further damage. It must always be remembered that if an accident is, through any set of circumstances, absolutely inevitable, it still remains the duty of the driver to face that accident and reduce its ill-effects to the minimum.

Remember, then, in all cases where it is a question of a "tight squeeze" not to glance first at one side of the car and then at the other, but go as close to the object on the right as you possibly can, and then, if there is in actual fact room to pass the other side will look after itself and you will get through successfully. If there is not room to pass no amount of looking from side to side could possibly help you; it only makes matters more difficult.

Steering Into An Obstruction—To Miss It.

There is one other little point which really quite frequently proves useful to those drivers who know it, and that is the apparent paradox of steering into an obstruction in order to steer out of it. This again is a situation which only crops up in tight corners and is as a rule only serviceable in saving a minor accident.

Sometimes it happens that one has for some reason or other to make a sudden dive from behind the vehicle just in front to pass it on the right but finds that there is not so much room on the right as one wishes in order to enable a complete sweep-out to be made. Say, for instance, that one has to dash out in this way from the rear of a street car and that on the other side of the road there is our old and imaginary friend the steamroller. Now, the distance between the street car and the steamroller, is, say, not very much more than the width of one's car. If the start of the steering manoeuvre referred to had been made in good time everything would be quite in good order and there would be ample room.

Suppose, however, that, contrary to instructions in previous chapters, the driver is hugging the street car in question and the driver of the street car for some conceivable reason has suddenly to apply all his brakes. The stoppage of that street car A, will be very much quicker than any ordinary motorcar B could possibly hope to stop. Therefore, it is a sudden swerve at the last moment, and perhaps one's front wings only just skim the rear of the street car and one feels intuitively that the back of the car is going to strike the bigger vehicle.

Now, it is rather natural to assume that to steer out as far as possible towards that steamroller, C, is one's only chance of making the best of the situation. In point of fact, however, such is not the case. When the car is about half-way past the dangerous "corner" of the street car the steering should be quickly reversed so as to make the direction of the

Digitized by Google

car a dive for the front portion of the street car and give a sharp but decided "dab" to the pedal brake.

This will have the effect of bodily swinging the rear of the car out anything from a few inches to a couple of feet, or even a yard, according to road conditions and weight, or lack of weight, at the back of the car, the tires in use, etc. The manoeuvre sounds a difficult one, and admittedly it is not a novice's feat, but at the same time it is a perfectly sound piece of driving, not, of course, to be used for the benefit of amusing people, but to be resorted to in cases where circumstances, over which perhaps one has absolutely no control, have rendered the choice of such a manoeuvre or an accident inevitable.

Steering Points in Epitome.

Summarizing, then, as a general rule, give vehicles which you are overtaking reasonable room, and allow cyclists, and more especially if the road is greasy, plenty of room. So far as passing cars going in the opposite direction, reasonableness is here again the keynote of instructions. It is to be feared that many drivers are in the habit of hugging the middle of the road and leaving the other one to go into the gutter. This is bad driving, and the writer must confess that in such cases he does likewise, generally to the final disconcerting of the other driver, who usually makes somewhat of a wild swing away to his proper side of the road at the last moment.

Such, however, should not be the case, and both should take to the side of the road so far as may be necessary to leave, say, a yard between the two cars. It is ungentlemanly behavior and bad driving to force the other man into the gutter, or to cut him too close.

Those who are tempted to adopt this bad type of driving (it is to be assumed that they have unknowingly got into the habit of it because respectable folk should always share the necessary "giving way") may find every now and then someone who is more at home with an inch to spare between the two cars than they are, and in such cases they may find themselves forced—as they think, in order to avoid an accident—to make a sudden swerve just as the two vehicles are meeting. The other driver, however, who is only endeavoring to teach them a lesson, is quite comfortable and knows that he is just missing the other car and is not at all worried. Let the motto then, when passing a vehicle going in the opposite direction, be that both give way a little, which is, of course, precisely as it should be.

Remember always to steer gently and in good time, not leaving the movement to the last moment, when it is necessary to steer suddenly. In conclusion, on no account ever move the steering wheels through the medium of the steering wheel when the car is stationary. It is a very bad practice and imposes an excessive strain on the steering gear, which it is neither designed nor intended to take.

If wire terminals break off and become lost make an eye as follows: Remove enough insulation so that the bare wire may be turned around the sharpened end of a pencil, and the end wrapped around the wire itself. This alone makes a good terminal, but it will be much improved if it can be dipped in melted solder.

GEAR CHANGING.

The Change Down Is Considered Most Difficult by Most Drivers.

In viewing the aspect of the case of gear-changing when going to a higher ratio, we have seen that it is the easier part of the work, the chief desideratum being a pause before making the change, which in most cases is provided automatically by the nature of the movement to be made, so that very much skill is not needed in effecting these changes in a reasonably good manner.

A four-speed gearbox has been dealt with, as it is easier to argue from the four to the three than vice versa. The only difference worth recording is that with a four-speed gearbox the pauses to be made are less than with a three-speed gearbox, as the difference between the ratios is naturally smaller. There is another small point, which may be mentioned to complete the substance of the main variations, and that is the necessity of taking into consideration the diameter and weight of the revolving portions of the clutch mechanism. If they are heavy then a longer pause will be necessary. If they are light the momentum stored in them is not so great and they will come to rest more quickly, and consequently a shorter pause is requisite.

Finally, there is the question of the clutch stop which has to be considered. It is provided to minimize the pause which is requisite, and there, of course, the same line of argument carries weight. If the clutch stop is efficient, the pause will be small; if not, slightly longer. In some few cars, within the realm of the writer's practical experience, the clutch stop is so efficiently arranged that a deliberate pause is quite unnecessary and the movement can be made almost as quickly as one cares to make it. This question of pausing must not, of course, be overdone, as, if it is, it is often a more difficult matter than it is when going too quickly. Occasionally one does do this, and finds difficulty in making the change up, and under these circumstances the only thing to do is to leave the change speed in the neutral for a moment and slightly accelerate the engine and have another go.

As to the precise moment in which to make the change gear upwards, it is rather difficult to lay down a definite law. The writer makes a practice of changing up on what may be termed a "rising note." That is to say, observe if the "hum" is on a rising scale, and the change should be made shortly before this becomes a fixed tone. If the car is kept on the low gear until such time as the fixed tone is brought into being, the gear change will always prove a difficult one, and one that necessitates a fairly considerable pause. Briefly, this means that on the level the low gears are not left in engagement for very long, and, excepting on a very steep hill, it generally means changing up again before the actual summit is reached.

In conclusion, always remember that, under any circumstances, if the time of changing gear is not successful and a grinding noise is the result, do not force the gear in, but try again gently. If the cause is through too long a pause it is better to go back into the gear which one is endeavoring to get away from, and make an attempt to change into the next one over again. Never force the gear lever.

Digitized by Google

Trick Changing.

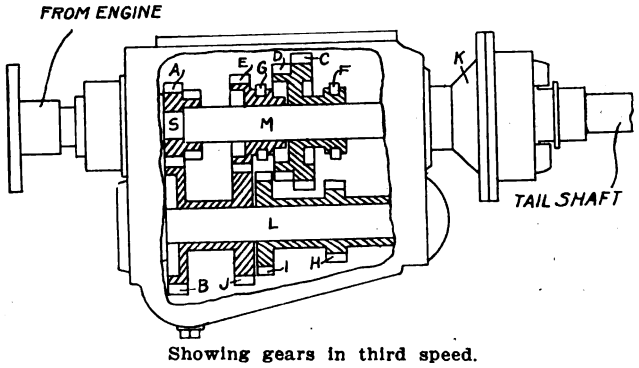
As a general rule it is safe to say that the clutch should always be partially or wholly disengaged for gear-changing. As a matter of fact, however, gear-changing can be effected without disengaging the clutch, although the writer would certainly be the last to advocate a general adoption of such a manoeuvre. For the sake of example, however, one can, while the car is accelerating well, suddenly close the throttle, which causes a very momentary over-running of the engine by the car, and this considerably reduces the pressure between the teeth of the wheels in the gearbox which are transmitting the drive, and so enables the lever to move them out of engagement without undue force. The movement, if properly executed, will on some cars really make a thoroughly good change.

However, this sort of gear-changing should not be attempted by the novice or even an ordinarily good driver, and experts would be better advised if they left it alone, as it must inevitably put more strain on the change-speed mechanism than when it is moved with the clutch disengaged.

Changing Down.

It is in the changing down that the majority of drivers find their greatest difficulty. We will deal again with a four-speed gearbox, as the advice in connection therewith may, when taken with minor modifications, be held to refer to a three-speed gearbox also. The state of affairs is now entirely opposite to what it is when changing up, and, instead of making a pause, it is necessary, in order to make a good change, to accelerate the layshaft. Now, there are several ways of doing this, but the whole of the writer's experience has tended to confirm his original belief that the double declutch method is better, and more universally reliable than any other, consequently the advice will be mainly restricted to this movement. Therefore, in the vernacular, we will "tick off" the method of layshaft acceleration, which will not be recommended for general use, quite briefly.

The Slipping Clutch Change.



Instead of wholly disengaging the top gear to go into the third, the clutch is slipped, and the gear lever can then bring the gears out of engagement against this slipping drive. When the two gear wheels are quite disengaged the layshaft is automatically speeded up by the engine running faster, and the next gear can be engaged. In many cases this works quite well, but in a good many more it does not, and it must always entail a certain amount of wear on the clutch which cannot benefit it, and also a certain amount of strain on the gear change mechanism, which is likewise sure to be the reverse of beneficial.

The throttle is, of course, left pretty well open, but the movement, even in the hands of an expert, is not always so successful as expected. Some people argue that this is the quickest way of changing in a scientific manner, but the writer, while giving due deference to the other opinions, does not altogether agree. Admittedly, the movement is simpler than that which is going to be primarily advocated, but it is necessary to make the declutching movement with a certain amount of deliberation an care, and also to make the depression movement slowly: thus time is taken up. So much, then, for the slipping method of changing down.

How to Double Declutch.

It must be admitted, before starting to describe this, that it will sound a little complicated on paper, but when once mastered the action is almost instantaneous, and the writer, without wishing to appear in any way to vaunt his prowess, has accustomed himself so to do it that the several movements are accomplished so quickly that occupants of the car are frequently difficult to convince that the series of movements have actually been accomplished. As stated, this is not meant in a boastful manner, but more to encourage the novice to study the movement and practice it, and not to be frightened by it.

Assuming, then, that we are running along at a good speed on top gear and encounter a hill. It is obvious, even at the bottom, that, before we can surmount it, it will be necessary to change to at least the third gear. Well, instead of waiting until the last ounce of the engine's power has been expended on the top gear, and then making the change when it is comparatively easy, we are going

Showing gears in third speed.

to show how it can be made at any car speed and any engine speed with perfect precision and silence. The movements may be enumerated thuswise:

1—Declutch and allow the accelerator pedal to come up to the ordinary slow running position.

2—Gear lever to neutral.

3—Let the clutch in and accelerate the engine by depressing the pedal for, say, a full second.

4—Clutch out, and gear lever into the third speed.

5—Let the clutch in again and accelerate in the ordinary manner.

One must admit that, written out in full, it is in appearance rather complicated. The whole series of movements, however, can, when one is really familiar with them, be accomplished well under two seconds, which, if one is to make a scientific and silent change at any required engine or car speed, is not an excessive time in which the car is to lose momentum. The neutral position has to be regarded as if it were another gear between the top and the third, though in practice, of course, it is nothing more than a mechanical movement utilized to serve a scientific purpose.

Let us now come to our diagrams again and find out the why and wherefore of the movement in theory. In top gear we have the wheel (e) in engagement with the dogs on the wheel (a), the only connection with the layshaft (1) being through the medium of the constantly meshing pinions (a and b). We remember, however, that the wheel (a),

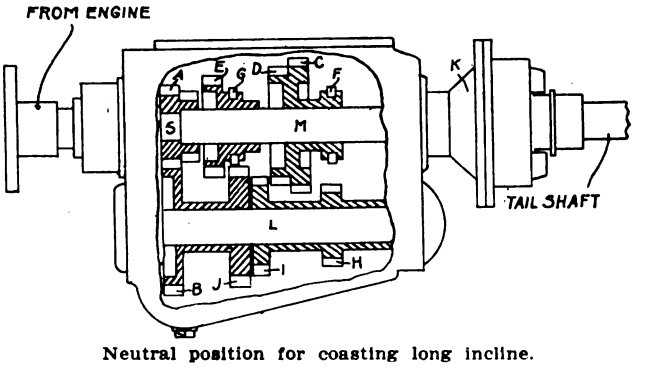
Digitized by Google

if revolving at 1,000 r.p.m., means a speed to the wheel (b) and the layshaft of only 500 r.p.m. Now, to come from this top gear into the third, it is necessary to engage the two wheels (j and e). We remember, however, that j has 30 teeth and e 30 teeth, so that, in order for a change to be effected silently, the speed of the layshaft (1) must be in a proportion of 30 to 30, or, in other words, must be just the same speed as the primary shaft, which is, of course, 1,000 r.p.m. Assume, then, that we are going along with the wheel (a) (and therefore on top gear of the wheel e) doing 1,000 r.p.m., and it is desired to change into the third gear. Then, if we assume that the loss in momentum is such as to bring the speed of the wheel (e), which, of course, is connected all the time to the tailshaft, down to 850 r.p.m., then in order for j to mesh with it quietly it must be going at just this speed, in other words about 850 r.p.m. We remember, however, that when the engine is doing 1,000 r.p.m. the layshaft is only doing 500 r.p.m. We see that for a good change to be made, it is absolutely necessary that the layshaft should do about 850 r.p.m., in other words, to go faster. Herein lies the whole secret of the movement, and while the gearbox is in the neutral position the clutch is let in and the engine accelerated, so that the layshaft is speeded up to the requisite amount to allow the change to be made scientifically and silently.

In any gear change made within reasonable limits this method will always be found effective. In fact, one may almost say that it is so without any qualification, as to change into the third speed when the engine was doing its utmost on the level would be quite an unnecessary procedure, and also a foolish one. Even under these adverse circumstances it can be done, unless the car is actually on the down grade, because the engine will always run faster when disengaged than when driving the car.

As we have so fully gone into the necessity of having this balance of speed between the wheels mounted respectively on the primary and secondary shafts when we were studying changing up, it is unnecessary to go through the other gear changes downwards.

Exactly the same line of procedure is to be followed. In each case the layshaft wants speeding up in order to enable a silent change to be effected. On a four-speed gearbox the amount of speeding up requisite is naturally less than a three-speed gearbox, and in some three-speed gearboxes, where the drop from top to second is a very big one, quite a large amount of speeding up is requisite to make a silent change at speed.



How to Learn It.

This art of double declutching is the one question above all others which the writer would ask those of his readers who are not already quite masters of it carefully to study and successfully to learn. Superficially, it seems a little difficult; but when one masters it it is the acme of simplicity, and one's feet and hand operate in perfect sympathy and without a shadow of thought from start to finish of the manoeuvre. First of all try it quite slowly, sitting in the seat of the car without the engine running at all. Merely practise the proper series of events and practise them until they can be accomplished in the proper order without anything in the nature of a stop from one movement to the other. When this has been learnt, essay first of all to make the attempt on an easy gradient, whereon a change from the top gear is not even necessary. Do not do it at great speed. Try for sake of example first of all at 15 miles per hour. When fairly practiced in the movement under these conditions, then try it on ordinary hills where a change is requisite, and when finally proficient it will be found that a change from top gear to third can be made just as easily and accurately at 30 miles per hour on a steep hill as at 15 miles per hour on a gentle grade—and always quietly to boot.

Coasting.

Coasting is not really a portion of the work of gear-changing, but the question of how to coast may suitably be considered here, relatively to a long down grade under average touring conditions where one does not wish to "blind all out," with the engine accelerated to its utmost. People frequently declutch and let the engine thereby run at its ordinary slow-running speed. However, the mere fact of holding the clutch out for a long period on end is always fatiguing in a greater or lesser degree, while it is likewise putting unnecessary strain on the clutch withdrawal mechanism and its usually unfortunate ball bearings (how many people think regularly to lubricate these bearings?).

Both these defects can be overcome when coasting by declutching in the first case, and putting the change-speed lever into the neutral. So far this is

Neutral position for coasting long incline.

the acme of simplicity, and on a nice road of fancy we will continue the coasting until we arrive safe and sound at the bottom of the hill, when the road conditions are such that it is necessary to call upon the engine to take up the drive again. We are faced with a little problem. How are we going to get a gear in again and which one?

Coming back to theory, if we study the illustration in the neutral position we see that the primary shaft (m) is being driven by the tailshaft, and no gears are in engagement, except the constantly meshing pinions. Now, the tailshaft may be revolving at, say, 800 r.p.m., which we will assume to be the equivalent of about 20 miles per hour. As the engine is only "ticking round," the gear wheel (a) is probably only turning at about 200 r.p.m. Obviously, then, if we endeavor to engage the wheel (e) with the dogs on the wheel (a) under these circumstances we are in for trouble. One obvious solution to the difficulty is to wait until the wheel (e) has slowed down to 200 revolutions, which, of course, would be silly, as it would mean waiting until the car is only crawling. Why not accelerate the wheel

Digitized by Google

(a) up to 800 r.p.m., which can be done quite easily by depressing the accelerate pedal?

The latter course is the one to be adopted, and practice alone can train the driver to know by the "feel" through his body, or the sound of his engine, the approximate speed at which it is running, but it is really not so difficult in practice as it would seem in theory.

It is generally easier to over-accelerate a little and then wait the necessary moment or two while listening to the sounds which tell of the reducing speed of the engine, and then with the clutch disengaged gently move the change-speed lever into the top-speed gear notch. To learn this, again try at slow speeds on the level. For instance, amble along gently at, say, about 15 miles per hour on the top gear. Declutch and put the change-speed lever into the neutral. Coast for about 20 yards, accelerate a little until it is thought that the speed of the engine is above what it would be if it were driving the car in the top gear, declutch, wait a moment, and gently re-engage the top gear.

Practice alone can make perfect in this manoeuvre, but when one knows the car well perfectly quiet changes can be made from neutral into the top gear, or into the third if under extreme circumstances it should be requisite (naturally by greater acceleration), at pretty well any speed desired.

AUTOMOBILE ENGINE COOLING.

The Water Jacket, the Circulating System, the Radiator and the Fan.

From A. K. Schanze, before the Society of Automotive Engineers at Cleveland.—This paper will deal with water-cooled engines only; air-cooled systems will not be discussed.

The cooling system of the internal-combustion engine as now applied on a majority of passenger cars normally divides itself into four main units: the water jacket around the engine cylinders, the circulating system, the radiator, and the fan.

The order in which these have been named seems to be the order of their importance in the minds of most engineers, consciously or otherwise. It seems also that this is the historical order in which real scientific research and practical development have taken place on the cooling systems now in use.

The author is of the opinion that no order of relative importance can be assigned to these four divisions of the cooling system. They form a chain whose strength is only that of the weakest link, and wherever one of the four falls below its proper standard there lies in the system an imperfection that should be remedied.

Cooling systems give outward evidence of imperfections in two general ways; they overcool or they undercool. Of the two, the latter is far the more common.

Water-Jacket Problems.

The function of the water jacket is to carry such volume of water that it will take from the cylinder walls only that heat that cannot be converted directly into mechanical energy, and the accumulation of which would be destructive to the cylinder material. From such a definition it would appear that, given the number of heat units generated, the mechanical work to be done, and the heat units in excess of the latter requirement, a water jacket would be a simple matter to design.

Perhaps it is, but its simplicity is a secret in possession of a limited number of engineers. The author, during fan tests that he has conducted on cars of many different makes, has found only three or four apparently ideal water-jacket designs. In the main, water jackets leave some room for improvement.

The mere solution of the problem of what volume of water a jacket must contain does not give the answer to the cooling problem. The distribution of the water layers around the cylinder walls may be of even greater importance than the volume. Ignition takes place in the top of the cylinder, which is longest exposed to fire and becomes hottest. Modern engineering practice has placed the deepest layer of cooling water over the top of the cylinder, which is as it should be. However, it seems to be the foundry practice in some cases to interpose stiffening ribs or small columns on top of the cylinder, which act to retard the circulation, with the result that steam pockets seem to be formed. These are evi-

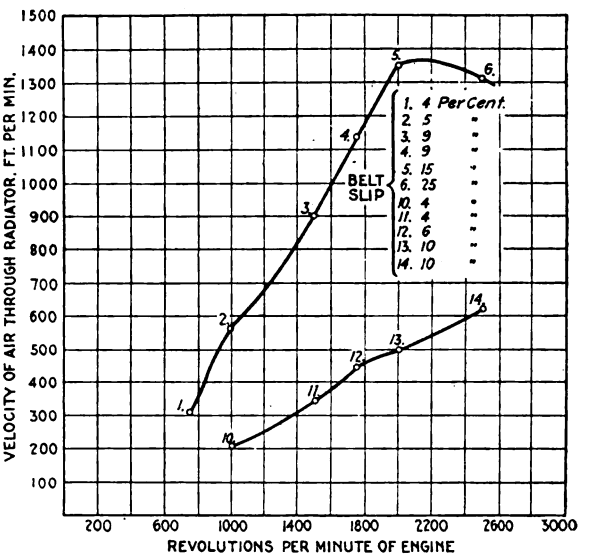


FIG. 1—AIR DELIVERED BY FANS AT DIFFERENT ENGINE SPEEDS

Fan speed, 1½ engine speed. Pulleys, 3 by 1 in.; belts, ¾ in. flat.

denced in some engines whose water-jacket volumes are adequate, in the sudden increase in temperature that takes place when the engine stops.

The author has noticed in several tests that when the engine was stopped the temperature recorded by a thermometer placed in the filler cap mounted 20 deg., from 200 to 220 deg. Fahr. We lost two thermometers through having them blown from an improvised bushing in a hole in the filler cap, a jet of steam shooting 20 feet into the air from a radiator the water in which a moment before had not been near the boiling point. Thermometers lashed in place indicated temperatures of 220 deg. Fahr. Repeated experiments could lead only to the conclusion that the whole mass of water was not being raised through that range of temperature in 40 or 50 seconds, but that some little patch on top of the cylinder was being converted into steam so fast that the filler neck, which was being used as a steam dome, could not act through the overflow to relieve the pressure.

Whenever a design of water jacket permits such a condition every effort should be made to get rid

Digitized by Google

of it. The condition is dangerous to the mechanical structure of the machine and also to people working around a car. The mechanical danger is present in radiators in which large areas and thin structures are not designed to carry pressures above the atmosphere. Steam above 212 deg. means such presures. Many a radiator manufacturer has undoubtedly been called upon to replace leaky radiators that were not really defective.

The danger to human beings lies in the possibility of a clogged overflow pipe and an unsuspecting person looking into the filler neck at the psychological moment. The author saw this happen about a year ago, when a man had his face severely scalded.

Tests conducted by authorities on internal combustion engines indicate that high compression contributes largely to the efficiency of the gas engine. High compression is always attended by the danger of preignition unless the cooling system can overcome the tendency.

If the cylinder walls are cool, the gas entering on the suction strokes does not immediately expand, fill the cylinder, and thus prevent the full calculated quantity entering. It tends to keep its density at a value in accordance with that established by the carburetor, and then the engine gives more nearly its maximum capacity.

In order to prevent the overheating tendency immediately following the shutting down of an engine, it would seem necessary then to give the water in the jacket such volume and distribution as to enable it to absorb the last heat accumulation in the cylinders, independent of the circulating system.

Jacket design, therefore, should be such as to allow liberal distribution of water and freedom of circulation. Since the circulating systems in general use are what may be classed as pressureless systems, the water will only follow the lines of least resistance within the cylinder. Short turns will at least materially resist circulation, and may even prevent it, and thus cause "steam pockets."

The design must be followed up by close inspection of the casting as it comes from the foundry. Too much stress cannot be laid upon this. The outside of a cored casting receives careful inspection to prove its freedom from flaws, but too often the inside is passed as being hopelessly inaccessible to inspection, and is assumed to be satisfactory if the exterior shows that there are no cracks.

Types of Circulating Systems.

Between the pump system and the gravity (thermo-syphon) system of circulation there is at present somewhat of a race for supremacy. The pump system frequently overcirculates, or tends to, while the gravity system undercirculates. Both faults are conducive to trouble.

In practically all pump systems the speed of the pump varies with the engine speed. This is logical enough, and conforms with good engineering theory and practice. Rotary pumps must attain a certain minimum speed before they do any effective work. This means that the starting point is considerably above zero, say about 250 or 300 r.p.m. Their efficiency increases after they get up to 500 r.p.m., usually until the speed is 800 or 900 r.p.m.; the result is that when the engine speed is such as to result in heating the pump, which was designed to do its circulating at a car speed of 20 m.p.h., is working at high efficiency. In such cases, however, the water is thrown up into the top of the cylinder and the radiator tank faster than the internal friction of the radiator will allow it to return to the pump. The bottom of the radiator is thus one moment empty and the next full, or it may be simply allowing a small part of the water to pass into the pump and a large part to be lost through the overflow pipes. When the radiator is thus, in part, deprived of water, it cannot perform the full amount of cooling action of which it is capable. Overheating, or at least inefficient cooling, results.

It would appear, then, desirable to select a pump speed designed to circulate the water within the limits of the radiator frictional resistance and then always run the pump at that, regardless of engine speed.

In marine work, circulating pumps are used in connection with the steam condensers in exactly the same manner in which they are applied to automobiles, and it has been found that pumps have to be controlled independently of engine speed. Such practice is now universal. The automobile engineer might well investigate the experience of marine engineers along these lines.

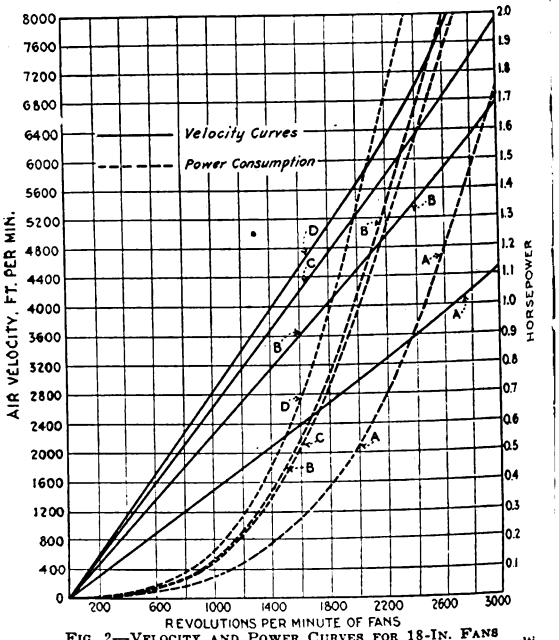

FIG. 2—VELOCITY AND POWER CURVES FOR 18-IN. FANS Curve *A*—Four-blade fan (flat blades). Curve *B*—Three-arm multi-blade. Curve *C*—Five-arm multi-blade (special). Curve *D*—Five-arm multi-blade (standard)

The gravity or thermo-syphon system of circulation, which is in its infancy as regards practical development, has been used with varying success. At best, its impulse is feeble, owing to the lack of head. On this account it succumbs readily to any abnormal frictional resistances that may result from solid matter in the water. It recommends itself because of its simplicity of construction, low initial cost, manifest economy of operation, and the advantages derived from the fact that it continues in operation for some time after the engine stops.

Its practical application to the car so as to realize these advantages is difficult. At present too many of these systems are arranged in almost the same way as the pump system, but with the pump

Digitized by Google

omitted. Best results in gravity circulation, as applied to the heating of dwellings and other buildings, are obtained with the horizontal runs comparatively short as compared with the head pipe. The principle is identical in the automobile. The head pipe must always remain well submerged. This latter feature cannot be accomplished without the use of a reserve storage tank attached to the top of the radiator.

Radiator Requirements.

After the body designer has established the shape of the radiator, and the purchasing agent has fixed its cost limit, the designing engineer can go as far as he chooses. Frontal area should be a maximum, and upon this depends net radiating area.

Radiating area can be considered from a horsepower basis, as the radiating action is exactly the process of doing work. Of the total heat of the engine absorbed by the water we have only to deal with the small residue that would cause overheating if not carried off by the radiator.

A cubic foot of air, in passing through a radiator and being raised 50 deg. Fahr. in temperature, absorbs 1 B.t.u. A horsepower represents 42.4 B.t.u. per minute, and upon this basis we can arrive at the other results.

The radiator, whose heat-transferring qualities are such as to give a uniform rise of temperature to all air passing through it, regardless of the velocity of the air, is an ideal not beyond our reach. Some are in existence that so closely approach this condition as to be considered perfect for all practical purposes.

For efficiency not only is it necessary to have the air passages free from solder obstructions, but it is just as important that they be of a size and shape that will give a good smooth run to the air. The more air that can be passed through a radiator the greater will be its cooling power.

We must also look carefully at the inside of a radiator to determine its capacity and the freedom with which water can circulate. On several occasions tests have shown that capillarity was preventing free circulation. This condition is too well konwn to radiator designers to need comment, but the fault does occur occasionally, and is probably due more to workmanship than design.

Core depths of as much as 4 inches are in common use, and have their purpose. Since expense is increased with core depth it is well to regard the radiator and fan together; moreover, the power of the fan will make a large difference in the core depth. Just what conclusions to draw on this phase of the subject the author is at a loss to know. It would seem that a 4-inch core was too deep for greatest efficiency, and this has at various times proved to be the case. Yet upon some tests conducted on two different makes of radiators the 3⅞-inch core proved to have greater capacity than the 3⅜-inch core.

As a practical suggestion to car builders, the author offers that every purchaser be furnished a special card cautioning him to keep the exterior of the radiator as clean as he possibly can. Much heating complaint would be avoided if radiators were kept clean. Tests go to prove that when a film of oil gathers enough road dust the radiator efficiency becomes about one-quarter normal.

Selecting the Fan.

Researches made by radiator manufacturers have shown that cooling varies directly with the quantity of air passed through the radiator, other conditions being uniform. It has, therefore, been the long-time hope of many of the radiator manufacturers that an improvement be made in fans.

Experiments conducted by the writer (see Figs. 1 to 5) have confirmed the theory that cooling varies directly with the quantity of air drawn through a radiator.

Some engineers place little stress upon the value of air as a cooling agent, except within very wide latitude. They apparently are of the belief that it requires a large increase in air delivery, say 300 or 400 per cent., to make any noticeable improvement in the cooling apparatus as a whole.

In contravention to this argument it need simply be pointed out that a certain time-honored practice among some engine builders proves that the contrary is the case. When engines are placed upon the dynamometers to be "run in" they are usually connected with their standard radiators, and carry their regular fans. Experience showed in some cases that this did not provide sufficient cooling to make safe running, so the simple expedient of placing an electric fan on a bench in front of the radiator and directing its air current into the radiator is resorted to with satisfactory results.

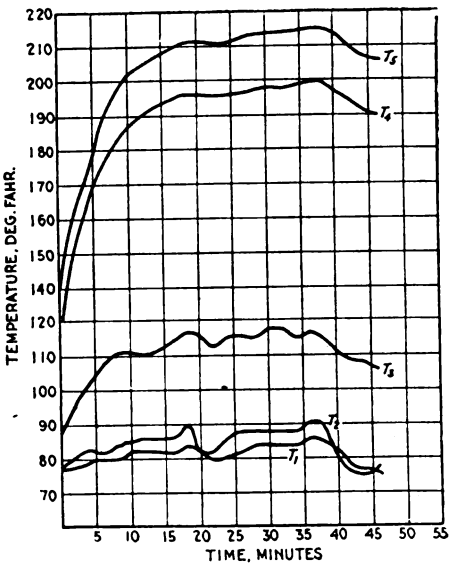

FIG. 3—VARIATIONS OF AIR AND WATER TEMPERATURES

T_1—Free air in room. T_2—Air entering radiator (4 in. from face). T_3—Air leaving radiator (¼ in. away). T_4—Water at pump. T_5—Water in top of radiator

Fan, five-arm multi-blade; diameter, 18 in. Engine speed, 1010 r.p.m. Fan speed, 1610 r.p.m. (3.4 per cent belt slip). Load on dynamometer, 12.6 hp. Velocity of air through fan, 1300 ft. per min. Radiator, diamond pattern. Belt, built-up V-type.

First and foremost in the selection of a fan should be considered the element of quantity of air delivery. The ideal radiator, as has been stated, is the one that will give off its heat at such a rate that the air that passes out of it can absorb no further heat units. In combination with this radiator the ideal fan is the one which will draw air through the radiator at such a high velocity that the air undergoes no measurable increase in temperature as it passes through.

The rate of heat transmission from one medium to another is directly proportional to the difference in the temperatures between the two mediums. This rule applies exactly between all the variations met

Digitized by Google

with in automobile practice. Therefore, the efficiency of a radiator and fan system combined would be greatest when the mean temperature of the air passing through the radiator were lowest; or, in other words, when the difference in temperature of the water in the radiator and the air passing through it were greatest.

As an illustration, assume the case of a radiator on a summer day, with atmospheric temperature of 85 deg., mean water temperature of 200 deg., and a rise in temperature of air passing through the radiator of 50 deg. The mean air temperature through the radiator is, therefore, $85 + 50/2 = 110$ deg. and the differential between the water and air is 90 deg. Heat will be transmitted in its proper ratio to this differential.

Take, then, the case when all other conditions are the same as in the foregoing case, but increase the air velocity 40 per cent., and thereby reduce the temperature rise from 50 to 30 deg. The mean air temperature through the radiator then is $85 + 30/2 = 100$ deg., and the differential becomes 100 deg. Heat will be transmitted at a faster rate in the proportion of 100 to 90, or an increase of 11 per cent.

The foregoing demonstrates that if one fan has twice the capacity of another it does not follow that a 100 per cent. increase in the engine-load capacity can be looked for.

As a matter of practice, then, the rule can be set down that the fan is of vital importance, and that the best fan obtainable should be installed. The question that follows is, What is the best fan obtainable? The answer to this is the fan that on any limit of diameter will give the maximum air velocity per revolution is the best fan.

Air velocity depends upon a fan's ability to build up pressure, and pressure overcomes the normal friction in the radiator and drives the air through at a velocity proportional to the square root of the pressure.

Fans of any one design increase their capacities in approximately geometric progression with the increase in diameter. Best practice would therefore suggest the use of the largest diameter possible on any particular model of car.

Classification of Fans.

There are several distinct types of fans offered by the various manufacturers, classified for description as follows: Rim fans, which are those whose periphery is bound by a circular rim; flat-blade fans, which are usually of three or four flat blades built out from a central spider; curved-blade fans, which are similar in construction to the flat-blade fans, except that the blades are curved somewhat after the manner of a garden trowel; and multi-blade fans, which are of two or more arms, up to six, and in which each arm consists of two or more blades.

Taking them in the order named, we note two types of rim fans, namely, those having a thin rim almost like a wire, and those having a broad rim equal in width to the sweep clearance of the blades. In the former type, as nearly as the author can ascertain, the rim is supposed to add strength in the resistance both to centrifugal force and to bending. It is also intended to act somewhat as a safeguard to the radiator, should the fan become bent or out of line and strike the radiator. In the latter type of rim fans it appears that the intention is to reduce noise.

The author has conducted air-delivery tests extensively on both types of rim fans and has found them very inefficient.

Flat-blade fans are the most common in use at the present day. They are usually of the four-blade type, built upon a central spider. Their air-delivering qualities are not good at low speeds, say a peripheral speed less than 5,000 feet per minute, consequently they have to be run at very high speeds. High-speed fans are noisy, and consume a large amount of power. These two factors will be discussed later in this paper. It is safe to say that the flat-blade fans are very efficient when working at peripheral speeds in excess of 15,000 feet per minute, which for 16 and 18-inch fans is close to 3,000 r.p.m.

Curved-blade fans, as a class, are similar in their construction to flat-blade fans; that is to say, they are normally built up on a central spider and are of three or four-blade design, generally. In capacity and efficiency they are much ahead of the flat-blade and rim fans for automobile use. Of course, they do not show a constantly increasing efficiency at very high speeds, 4,000 and 5,000 r.p.m., but then good engineering practice would counsel against the use of any such fan speeds where it were possible at all to get away from it. These fans are good because their efficient speeds are generally comparatively low, and they handle a considerable volume of air.

Only one multi-blade type of fan is at present in existence. This consists of groups of blades placed one behind the other, and presenting somewhat the appearance of two fans upon a single hub. Experiment has demonstrated that this is far and away the most powerful and efficient type of disk fan yet produced. The capacity is from 50 to 100 per cent. greater than that of other types, and its most efficient speed is from 800 to 1,200 r.p.m. for 16 to 20-inch diameters. It develops a high velocity pressure which drags air through the radiator even under adverse conditions. Its power consumption per cubic foot of air handled is at least 40 per cent. less than that of any other type of automobile fan it has been the author's experience to test. It also has another quality that recommends itself to the automobile engineer, namely, it develops a high suction at its periphery. This quality brings the edges and corners of a radiator into use. The advantages of this feature are self-evident.

Another type of fan very little used in the automobile industry, but worthy of notice in a paper of this kind, is the centrifugal fan. This is a fan that takes air through the line of its axis and discharges it in the plane of its perimeter. It develops a high pressure, but is of comparatively low volumetric capacity. On air-cooled engines it has been found satisfactory, but its adaptability to water-cooled systems remains to be worked out.

The engineer, in making his selection of a fan, should take into serious consideration the amount of power necessary to handle maximum air velocities through the radiator. This phase of the question has been considered by very few engineers. A study of the accompanying power curves will show that an astonishing amount of power can be used by a fan when its speeds are excessive.

Digitized by Google

Fan Power-Consumption and Speed.

Take, for example, the 18-inch fans for which the power, speed and air delivery are plotted. At 1,000 r.p.m. the flat-blade fan was delivering a velocity in free air of 1,423 feet per minute on a power consumption of 0.077 hp.

The multi-blade (five-arm) fan, at 1,000 r.p.m., was delivering air at a velocity of 2,580 feet per minute on a power consumption of 0.18 hp. under the same conditions.

Now compare this with what took place at double the speed (2,000 r.p.m.). The flat-blade fan handled air at 2,826 feet per minute velocity and consumed 0.524 hp., and the multi-blade fan generated

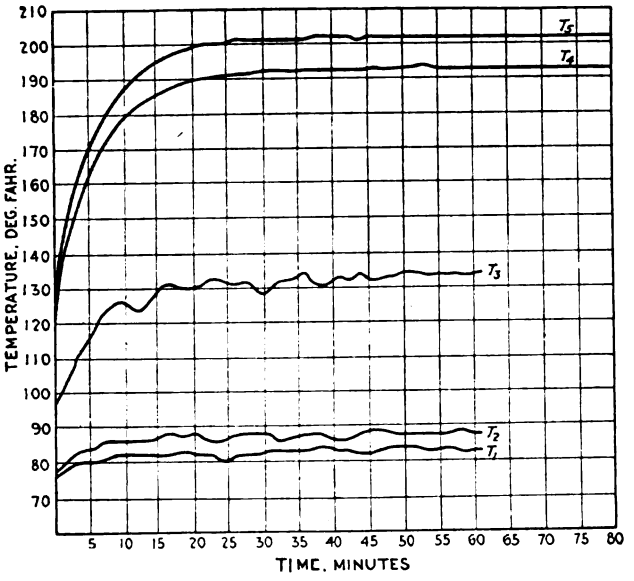

FIG. 4—VARIATIONS OF AIR AND WATER TEMPERATURES

Fan, five-arm multi-blade (std.). Diameter, 18 in. Engine speed, 998 r.p.m. Fan speed, 1591 r.p.m. (3.4 per cent belt slip). Load on dynamometer, 12.5 hp.. Velocity of air through radiator, 887 ft. per min. Belt, built-up V-type. Radiator, square air tube, 3¼ in. core.

a velocity of 6,060 feet per minute and consumed 1.4 hp.

The increase in power, it will be noted, was almost in direct proportion to the cube of the speeds.

Many engines are so geared that the fans at times are supposed to be making as many as 4,500 r.p.m., and the power consumption theoretically increases to 6 or 8 hp. It is the author's contention that such a power expended on driving a fan is completely wrong, and that its practice should be discontinued without delay. Engines running up steep hills or through heavy roads are frequently shifted into low gear in order to let the cylinders do the work possible at high piston speed. Under such circumstances, then, the fan is demanding one-sixth to one-eighth of the engine's power. This 6 or 8 hp. generates its quota of heat, which again has to be extracted. It is a good fan that will assume this additional burden without allowing boiling.

Fan Belts and Pulleys.

In looking at the situation from a practical standpoint we must investigate the medium through which this high power reaches the fan. This transmission is usually through either a flat or V belt. Can a leather or canvas belt, whose contact width is between ¾ and 1¼ inches, transmit much over 3 hp.? The best authorities on the subject say it cannot be done. This answer is probably correct.

Many pulleys in use are too small in diameter. While theoretically pulley diameter has no effect whatever on power delivery, it does have a material effect on belt slip, and consequently upon fan speed. Much fan trouble arises from this cause.

The experience of belt makers shows that a pulley should never be of a diameter less than 30 times the thickness of the belt. This is practically out of the question in most automobile designs, as it would necessitate a 4-inch pulley. However, the fault of going to the other extreme and using a pulley 1½ to 2 inches in diameter should be corrected, and must be before the automobile manufacturer can feel assured of getting the designed performance from fans. A minimum diameter of 3 inches is earnestly recommended.

Much remains to be done in selecting belts, and from recent reports it appears that some types of V belts are giving superior service.

Experiments conducted by the author demonstrated that with a 1-inch flat belt a 15-inch fan could not be driven at a speed greater than 3,200 r.p.m. without a large percentage (over 30) of slip, which soon proved destructive to the belt.

The summary of the whole situation, then, is that when the engine gets beyond a certain speed, so that the fan makes 4,000 r.p.m. or over, the belt begins to slip, and once this condition has set in the fan becomes worse than useless. A slipping belt does itself much harm, and in addition polishes the fan pulley so as to make the percentage of slip at normal speeds greater.

Disadvantages of High Fan-Speed.

Several hundred thousand cars are built annually in which fans are so connected as to develop a speed of from 2,000 to 2,500 r.p.m. when the car speed is 20 m.p.h. These cars, most of them, do not show a tendency for the engine to heat when traveling over smooth roads at that speed, but they do when making from 30 to 40 m.p.h., or when the engine is doing the same amount of work in one of the low gears. Then, at just the time when the cooling agents are most in demand, the fan is either slipping, or using an amount of power not at all commensurate with its cooling power.

In fan practice, both in the ventilating and in the automobile trade, it has been pretty well proved that all fans become noisy when their top speed exceeds 5,000 feet per minute. At any speed beyond that there is bound to be noise, which increases with the speed. When 16 and 18-inch fans are running at 2,000 r.p.m. or more they are far above the silent-zone speed. In many cases they produce sounds much resembling a sawmill.

When a car is racing at 35 or 45 m.p.h. the driver is too busy to notice the objectionable noises, but when the same car rolls down a smooth city boulevard at 20 m.p.h., and all of the other mechanisms are practically noiseless, it is somewhat incongruous to have a little 2 or 3-pound fan making all the fuss.

The demand from engineers who build our standard cars is daily becoming more insistent for less noise from the fan. The only way for this demand to be met is to bring the fan speeds down to somewhere within reasonable limits.

The apparent obstacle to meeting this demand

Digitized by Google

successfully is the fact that, generally speaking, fans in use today will not deliver much air until they are buzzing at tip speeds of about 10,000 feet per minute. It is to be hoped that automobile engineers will make fan builders produce better fans.

Everything points to the necessity of reducing the fan speed; wear on bearings and belts, noiseless operation, and, most of all, conservation of power, demand fans that can deliver the air at lower speeds. In short, we must have better fans.

Types of Fan Bearings.

Bearings are of several distinct designs: the plain iron or steel bearing, similar to an ordinary wagon wheel on its axle; the bronze bushing on the steel spindle; the cup-and-cone ball bearing; the roller bearing; and finally the annular bearing.

The iron hub or steel spindle bearing satisfies the demand for a low-priced bearing. It gives satisfaction of a certain kind, but it is subject to and does have so many troubles that it really should not be used.

The bronze bushing on the steel spindle is good enough in its way, but it costs real money when properly made, and has a tendency to let its lubricant run out at both ends and spatter things with grease. The saving in cost over one of the types of roller bearings is so little as to make it hardly worth while.

The cup-and-cone ball bearing has been the most widely used of the so-called "better bearings."

The author has never been able to comprehend just how this type became so popular since its basic principles are wrong for most fan applications. For shafts or spindles that present a uniform vertical thrust the balls take the load in a normal line because their obliquity to the axial line is compensated for by the opposition of one set to the other. Such is the case in motorcycle and bicycle axles. The belt on fans exerts a heavy downward pull, usually from the line half way between the cups and the fan, then exerts a thrust at right angles to the belt pull. The whole arrangement, therefore, seems wrong.

The cup and cone bearings apparently are always looking for trouble. As a matter of fact, a good cup and cone bearing ought to be the most expensive kind to make, but again the element of reduction in first cost has influenced conditions to a point where the greatest criticism that can be made is of the quality of the materials used.

The annular bearing is the ideal for those who are willing to spend the money for quality. Good annular bearings cause no trouble and good ones can be found. They are noiseless, and reduce friction to a minimum. They can also take up the thrust without the interposing of thrust washers. The automobile engineer should, however, look out for cheap imitations as there is a wide difference in quality among the many makes of annular bearings. The best that can be had is none too good.

Roller bearings of several types have been offered for fan use. The application of these on fans has been comparatively limited, but there will be a decided increase in their use during the next year. One make in particular has stood the test of continuous running and meets the price qualifications within reasonable limits. It consists of a series of helical steel rollers held in place by two end disk washers. The latter are rigidly held in their planes by small rods that also serve as spacers between the rollers. The whole presents the form of a hollow cylinder 2 inches long. This is placed over a carefully machined steel spindle. Into the pulley hub is inserted a seamless or split steel sleeve that acts as an outer path for the rollers while the steel spindle is the inner path.

It is earnestly recommended that this subject be considered by the society with a view to standardizing one or two types of bearings. The engineers could then write uniform specifications and fan makers would be free to devote more effort to the fans proper.

Applications of Fans.

Taken, then, as a whole unit, the fan should be considered with all the care given any other part of the car. Other parts of the chassis and body should be constructed with a view of letting the fan do its

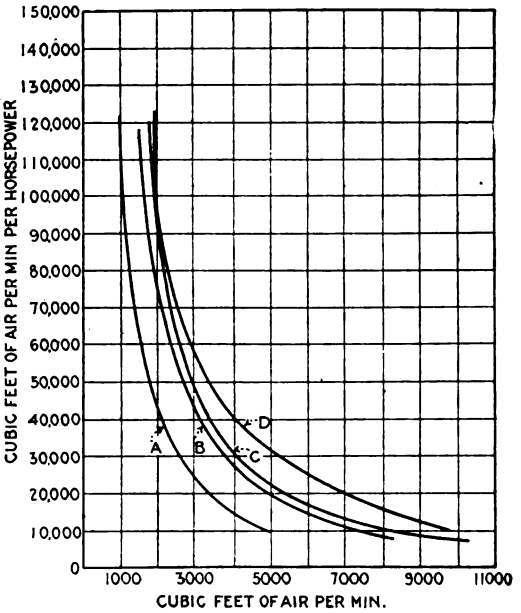

FIG. 5—RELATION OF HORSEPOWER AND FREE AIR DISCHARGE BY 18-IN. FANS

Curve *A*—Four-blade fan (flat blades). *B*—Three-arm multi-blade. *C*—Five-arm multi-blade (standard). *D*—Five-arm multi-blade (special)

work in the most efficient manner. Assuming, now, that a fan has been selected, the nature of its application must be studied.

The air intake through the radiator should present as little friction as possible; there is a wide difference in this respect. The distance between the fan and the radiator should always be ½ inch.

The air "getaway" will bear much improvement, and such improvement can be made. For best results, the discharge area should exceed the intake area by at least 20 per cent. This rule assumes, also, that the discharge space will be in one location and unobstructed. No automobile known to the author presents such a condition. Moreover, in every car thus far measured, the discharge areas are less than the free radiator supply area.

Spaces under the dash are hard to alter, but plenty of louvers can be inserted in the hood, and these should be figured as the primary means of air escape. Why the car designer objects to louvers is not altogether clear, but their necessity is so great that appearance can well be sacrified.

The air passing through a radiator expands a

Digitized by Google

great deal under the hood. With an inadequate escape area, the static pressure builds up to a point beyond the fan capacity and relieves itself by backing out through the radiator.

To overcome this, shrouds have been placed around fans in some cars. The effect is then to increase the air distribution over the front of the radiator, but the shrouds are inefficient because of the sharp angle they necessarily make with the rear face of the radiator; furthermore, they cannot increase the capacity of the fan.

The air velocity will be greater than it was through the deep radiator because the friction has been reduced. Thus the fan has even more than compensated for the reduction in core.

TO WOMEN FROM A WOMAN.

Good Advice for Either Women or Men Automobile Drivers.

From Mrs. A. Sherman Hitchcock, Rhode Island. —Every woman who intends becoming the driver of a motor car should familiarize herself thoroughly with the rules of the road and traffic regulations and never deviate from them. There would be fewer motor accidents if they were all operated in strict accordance with the rules I am about to give.

Pass any moving vehicle going in the same direction on the left. Even if there is room on the right always pass to the left. Do not attempt to pass anything unless you can see a clear fifty yards ahead. If obliged to pass to the left of a trolley car, whether it be standing or in motion, be sure the view is unobstructed and do not pass a standing trolley car without slowing up or stopping entirely; also be sure to give warning. Do not attempt to pass a vehicle going in the same direction when about to turn a corner or curve. Someone may be coming from the other direction. Better wait until the view is clear. If another vehicle is trying to pass you, keep well to the right. Do not pass anyone on the street whose back is to you without giving warning, as they may step backward at any moment.

In turning into another street do not cross from right to left without looking back. If another car is following hold out your hand. Traffic from a by-road in all cases gives way to that on the main road. Unless you can see 100 yards clear both ways when coming from a by-road to a main road, come very slowly and sound your horn. If there is other traffic on the main road it is for you to keep clear of it, and not for it to keep clear of you. Never approach a curve at greater speed than will permit the car to be stopped within its own length. Nobody knows what may be coming in the opposite direction, and if anything is coming the chances are its driver will not be observing the rule of keeping to the right. Take all corners slowly. Those you think you can see around may conceal a child. Take all corners to the right as close to your own side as possible. In taking corners to the left keep as close to the right side of the road as possible. The sharper the turn and the more difficult it is to see around, the slower the pace must be and the more necessary it is to observe these rules.

Be careful about running fast on slippery or sandy roads. Even the experts are careful in such cases. Remember that even non-skids will slip upon a very dry road if you are taking the corner at high speed. They will also skid freely upon wet asphalt. A front-wheel skid calls for the application of the brakes; a back-wheel skid never. If your car be given to skidding upon the front wheels, have a non-skid upon the off fore-wheel. It will hold you around the corners. Tires are saved by coming slowly over the top of a hill before the descent begins, taking corners slowly, and using the brakes gently. Tires are injured by coming fast on to a descent and then checking; by going fast around corners and putting on brakes hard and suddenly, or in starting too fast or with a jerk.

Keep in the middle of the road. You can't run into a ditch unless you first get dangerously near to that ditch. Avoid any spot in the road or at its side where underbrush appears. Underbrush thrown on the road often covers dangerous holes. Underbrush growing at the roadside is very likely to have its roots in a ditch that means trouble if your car approaches too near. If the road is narrow and you are approaching another vehicle, slow down. When you see any likelihood of a horse becoming restive, stop. If necessary, do this even before the driver holds up a warning hand. Horses have become so accustomed to motor vehicles that it is seldom necessary to be obliged to stop, but when touring one is quite apt to encounter cases of this kind and it is well to always act quickly before there is any possibility of an accident.

It is unwise to leave your car on an incline, even with the brakes on, unless the front wheels are turned to the curb. You can never tell who may release the brakes. Never let your car stand on a hill. The average country road hill is never too wide at best and traffic needs all the available room, without having any part of it taken up by a car that could just as well stand at the top or bottom. Never let your car stand at a curve in the road. Another car rushing around the turn may ruin it and maim and kill.

Do not look backward unless you are sure that no vehicle is in your immediate vicinity ahead. Always be very sure regarding railroad crossings and never, under any circumstances, take the least chance. Some of the most deplorable accidents with much loss of life have resulted from the driver not being quite sure that all was safe. Approach all crossings carefully and when a guard is stationed at the crossing obey his signal, otherwise slow down and make absolutely sure that no train is approaching from either direction. The fatal accidents resulting from this one thing seem especially dreadful when we realize how easily they might have been averted.

Test your brakes every morning. Read and study the traffic laws of your city and State. Respect the rights of pedestrians. Keep within the speed limit. Always remember that it is better to cause a delay than an accident. Life is too short to take chances.

A source of noise that is frequently overlooked is the case covering the timing gears. It should be kept filled with lubricant, but if it becomes empty it acts as sounding board and intensifies the noise of the gears.

WHY NOT BE PROUD?

There was never a greater slander than to accuse us as a nation of vanity and self-glorification. If the United States is given more to these qualities than either Germany, England or France, then we fail to see it, but if this is a proud nation there is abundant reason for it.

We have more than 100,000,000 people. Our territory touches two oceans a thousand leagues apart and stretching through all productive degrees of latitude. We can grow every product of temperate and torrid zone. There is nothing that enters into the consumption of civilized life that we cannot produce. We can raise wheat enough to feed the world; corn enough to supply its wants; cotton enough to clothe it; cattle enough to supply it with meat. We have coal fields enough to warm the world; petroleum enough to run its engines; timber enough for twice over our needs; gold, silver, copper and iron practically inexhaustible; fisheries that swarm with food—enough for ourselves and as many more. We can grow better apples and better oranges than can be found in all Europe or Asia.

We have made more automobiles than all the rest of the world besides, and our people are using three times as many as the world elsewhere is using. We have laid nearly as many miles of railroad and stretched quite as many miles of telegraphic and telephone wires as in all the world put together.

Our internal commerce is simply stupendous. Thousands of steamers may be counted on the Mississippi river and its tributaries, and the great lakes are dotted with the largest of craft, loaded with our own products.

We have the largest seaports in the world; factories that can spin and weave all this nation and several others can wear; shops that can make all our shoes and many more; furnaces that can smelt and forges that can roll all the iron we can use, and supply much to other less fortunate nations.

We can make any article of machinery from a tiny watch to the biggest engine. And what a contribution to the world's agriculture are our harvesting and farm inventions! We invented the sewing machine, the steamboat, the telegraph, the telephone, even the submarine boat that is just now being turned against us.

We give so liberally to charity, to education, and to religion, that it should inspire the admiration of all other civilized countries, and so much that our intellectual and moral culture are higher than those of any other nation in the world. More, indeed; we have taken nothing short of millions of the oppressed, down-trodden, poverty-stricken and ignorant citizens of the countries that criticize us, put them on their feet, raised them up, educated them, and made just as good citizens of them as they would let us.

Indeed, this nation may well be proud of what it has done, what it is, and what it is doing. If we are not proud of our government, of its keen sense of justice, of its power used so righteously in all cases, of its stability, of its amazing tolerance and unselfishness, then we ought to be ashamed of ourselves.

No good citizen will allow by word or deed any reflection upon the goodness or greatness of our common country.

ANYTHING THEY WANT BUT—

The grumblers and the discontented must not forget that in this country they can have any kind of government they want. In most countries they are obliged to take what is given them. Here they can choose for themselves.

If they want an I. W. W. government—whatever kind of government or lack of government that may mean—they can have it; if they want socialism they can have it; if they want a government where the utmost consideration is paid the rich and little to the poor, and where higher respect is paid to wealth than to talent or virtue, they can have that also; if they want an oligarchy they can have it; if they want a communistic government same as that which gave rise to the famous "reign of terror" in Paris, they can have it. If they want the single tax of Henry George, or free trade, or protection to our industries, or any of the other things that are so ardently desired by portions of the body politic, they can have any of them.

Yet there is but one way only to get any of these laws or forms or systems of government, and that is to secure a vote of the majority. And if the cause they so ardently champion is a worthy one, to get the necessary majority should not be difficult. Although the press may not always be depended upon to champion a cause or to oppose it, yet it can invariably be relied upon to spread broadcast the facts about it, so that the voters can make up their minds

Digitized by Google

easily whether they want it or not. No good cause need ever be lost, no bad one need ever be gained.

Let this not be forgotten, however: Woe be to any class, or clique, or gang, no matter how good or bad their cause, who imagine they can secure what they want by force, or threats, or intimidations, or lawlessness. If they can't get a majority of the voters of the country to believe as they do, they must either get along with things as they are or get out of the country.

BUSINESS WILL BE GOOD.

What is business? Why, it is simply supplying the people with their wants and needs. Business is not begotten in the bank, the counting-room, or the office; these are but the effects of business—the response to the cause. The man who makes business is likely to be in the shop, or on the farm, in the factory, or at the forge. He is toiling and moiling to get a good week's pay when Saturday night comes so that he can purchase some groceries and dry goods, and possibly go to the moving picture show or theatre, or, better yet, put something liberal into the contribution box at church on Sunday, or take a week-end trip with his car. He may have enough in that week's pay to purchase his wife or his daughter a new dress. He may be able to save up a few dollars from that week's pay for a home of his own, or for an automobile.

And all this makes business. In fact, it is about all there is to business—this matter of food and clothing and housing, and educating and uplifting. Take these away and there would be no business. In countries where they exist in the most meagre and penurious fashion only, there is little business.

Of course, business may be anticipated. That is to say, a man may produce something like an automobile, a piano, a plow, a suit of clothing—anything that the people need or desire—with a view that the prospects are favorable for its disposal and consumption. But it is as important to be assured that the people have the means or power to consume it as it is that they have the will or desire to consume it. The people always have wants and the desire to gratify them, but they do not always have the means to gratify them.

The off-hand remark: "Let business go on as usual" has little effect one way or another. It will go on without a command, and it will not be stayed by indifference. The only question as to business is whether you as a business man are going to get it, or whether you will allow it to pass on to some one else. That it will be done by some one goes without saying. All the people are working and consequently all are spending. There has not been a time for many years when the conditions for good business were more favorable than now.

Moreover, the thing that is absolutely necessary to the execution of business—money, a medium of exchange—exists in about the same volume that it ever has. It is true it has largely changed hands, but it still exists, and this change has taken it from the rich, whose wants and needs were already well supplied, and put it into the hands of the former poor whose wants and needs are not supplied, but who will liberally supply themselves now that they have the means.

During these abnormal times of war the production of things that people need has by necessity been largely curtailed, in order to give place to the production of the things needed for war. In addition to this, a large portion of the young and able-bodied producers of the civilized world has been withdrawn from productive channels. They are now consumers only. Thus it may easily be seen how pressing the demand must be for things the people want and need, and who likewise have the means to purchase them.

How can business fail to be good then, and whether or not the war ends soon or continues long?

Of course, lack of confidence and of optimism would delay production somewhat, but as far as we can see, these qualities strongly exist among business men. Producers are handicapped by the scarcity of raw material and by the pressing necessity of making war supplies, but the need of general production is imperative and it will continue to exist for some years or until the demand has been met.

This government is likely to spend on account of the present war anywhere from $10,000,000,000 to $20,000,000,000, and possibly much more. Some of this money will go abroad, but mighty little. Most of the loans to foreign governments are in the form of credits; the cash itself will remain right here. Probably three-fourths of this stupendous sum will be filtered along down among the common people, and there it will mostly remain until it is spent for comforts and luxuries—the things that keep our mills and factories and stores and farms full of activity. And this is what makes business.

A LESSON OF THE WAR.

The venerable president-emeritus of Harvard University, Charles W. Eliot, had a page article in a recent number of the New York Sunday Times, in which he says that the "best of the lessons" of the present war are that:

"Adequate production in manufacturing industries cannot be brought about or maintained without the abandonment of the doctrine of limited output, a doctrine long carried into practice by some important labor organizations."

The war has taught no such lesson. It has taught absolutely the reverse. The situation is this: The war has withdrawn much more than one-half the able-bodied men from productive channels in the countries engaged in it, and put them in the ranks of the consumers only. It has likewise put something like one-half of those left into the production of arms, ammunition, and other war necessities. And yet the amazing fact is that these countries are keeping production well up to the demands, even with this far less number of producers. Of course, young women have helped much to keep up the necessary production. They are employed in channels never dreamed of before. But having gone into it they can't very well be turned out after the war is over simply to find work for the millions of young men who will have to work in some form or another to get a living.

Being able to supply the pressing needs of the people during war time when such a large proportion of ordinary producers are either consuming only or at work on a kind of production that will not be needed after the war is over, the question arises, what about production and consumption when all the workers of the world, including the rank and file of women, are again producing the

Digitized by Google

things that people need of food, clothing and luxuries?

Why, production will so far outstrip normal consumption that every producing nation on earth will be eager to find some other nation that will purchase and consume its surplus. Dr. Eliot is greatly mistaken in his postulate. The doctrine of "limited output" will have to be followed out more vigorously than ever known after the war is over and as soon as the needs of the people have been replenished, or there will be such a congestion of manufactured goods of all sorts that prices will sink below the cost of production.

There will be only one way to mitigate this situation—only one way to find a market for normal production, such as will ensue with even a moderately limited output, and that is to see that the great mass of the people make sufficiently good incomes so that they can afford to purchase what they need, and to a limited extent also, what they desire and may not absolutely need.

THE UNEXPECTED.

Times like these bring out both the noblest and the meanest qualities in human beings and often where least expected. Take the matter of enlistments, for example. In one instance, a young man with a family, who did and said everything in his power to keep our country out of the war, was among the very first to volunteer his service for the army after war was declared. And although he was asked if he did not want a commission the officer in charge of the enlistment noticing at once his superior qualifications for such distinction, yet he replied that it seemed to him that the greatest need was for common soldiers and it was his desire to help fill that need. We may remark that the person we refer to has for some time been one of our valued contributors, but his modesty might not permit him to approve our mentioning his name. Another instance: This is the case of an only son, a sophomore in one of our well-known eastern colleges. He was anxious to enlist and first applied for a position in the navy and then for one in the army. Unfortunately, his eyesight was defective, and he was rejected. But nothing daunted, he next sought for a position in the ambulance corps, and his knowledge of a car and how to run it made his quest successful despite his poor eyesight. So he has now left college and will soon be in the field "somewhere in France." It is gratifying to note that despite the fact that he is the pride of his father and mother, and that they were bent on his acquiring a professional career, they were cheerful in the thought that their beloved son was to be of service to his country.

On the other hand, it is noticeable that many who complained loudly and bumptiously when strong efforts were being made to keep this country out of the war, seem to have now lost their patriotism and grumble at whatever sacrifices they are called upon to make for our common defense. It all goes to show that no one can tell what's in a man or woman until it has been called out or put to the test.

Expert chauffeurs don't care if their engine misses a cylinder once in a while so long as it doesn't miss a pedestrian.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

Ran Into a Train.—Near Red Bank, N. J., a woman having taken her husband to the station, stopped her car facing a train. When she started to leave the station, she forgot to reverse the engine. The automobile started ahead instead of backward and the woman lost control of it. The car ran over the benches, smashing them to pieces and stopped at the side of the train.

Fractured Her Skull.—Near Philadelphia, a young woman jumped on the running board of a car, driven by two of her men, intending to get off when she reached her home. When she got there, the car was not stopped; she jumped off and fractured her skull.

Caused by a Toy Balloon.—Near Little Falls, N. Y., the wind blew a toy balloon held by an infant, into the face of a driver of a car. This so disconcerted him that the car was pitched over a 50-foot embankment to the railroad tracks below. A woman was killed and the rest of the party were more or less severely injured. The car overturned several times before it landed and of course was completely demolished.

Plunges Into Creek.—Two cars came into collision near Seneca Falls, N. Y., and one had a front wheel torn off. The other swerved to one side, hit an iron railing and toppled over into a creek by the roadside, taking its occupants with it. When the car landed. it was bottom side up. The front was totally under water but the man was able to get his wife and children out from under the car, and strange to say, they were not fatally injured. The owner of the car says he cannot see how his family was saved from death.

Trapped on the Railway Track.—Near East Foxboro, Mass., a lad ten years old was killed when his father's car was trapped upon the railway tracks. The further gate guarding the tracks having been lowered after the car was allowed to pass the first gates—the driver of the car saved himself by jumping for safety, but his son's body was thrown into the air and hit by flying parts of the machine. It is claimed that the gates worked improperly, and moreover, that the train was going at a tremendous speed as it approached the crossing.

His Hat Blew Off.—Death interrupted a wedding near Joliet the other day, the bridegroom having been killed while on his way to meet his fiancee. The man was a little late and his hat blew off. With one hand on the car, he stooped over and attempted to catch it with the other hand. He slipped and fell under the wheels. He was immediately killed. At the time of the accident, he was riding on the running board of the car.

A Lunatic at the Wheel.—Four were killed and seven injured in a head-on collision of two automobiles near New Bedford, Mass. A patient of a lunatic asylum on parole had seized the wheel of one of the machines and twisted the steering gear in the wrong direction. It plunged into an approaching car and scattered the occupants of both cars in all directions with the result as stated above.

Struck by a Fast Train.—Certain occupants of an automobile were hurled into the air at Port Clin

Digitized by Google

ton, N. Y., and six of them were accidentally killed. The car is said to have stalled on the track when the collision came. One young woman landed on the locomotive and was carried a quarter of a mile before the train could be stopped. There was neither watchman nor gates at the railroad crossing.

The Axle Broke.—Two young men were in a car near Auburn, N. Y., and as it went over a railroad track at high speed, the axle broke, making the steering gear useless. The car turned over twice and one of the young men was killed.

When Too Near an Embankment.—A big car filled to its utmost capacity, slipped off the side of the road near Los Angeles, Cal., rolled into a ravine and struck a tree. One man was killed and his two sisters were seriously injured. It appears that the road was wide enough but the driver must have carelessly gone off near the edge. The machine turned over and went some twenty or thirty feet below.

Skidded and Turned Over.—A girl was killed near Schenectady, N. Y., when an automobile in which her mother and two brothers were riding, skidded and turned over three times. The rest of the party was seriously injured but it is expected they will live. It appears that another car was approaching and that a bicycle was also in the road. In some way, the car was driven so far to one side of the road that it skidded and turned over.

Dropped into a Hole in the Road.—A man and a girl were killed in Brooklyn, N. Y., when the car they were riding in crashed through a fence protecting an excavation and fell 50 feet to the bottom. Two women escaped with slight bruises and the man also jumped and also escaped but the driver of the car and a young woman were instantly killed.

Hit the Side of a Bridge.—Two were killed and two injured when a car hit the side of a bridge near Lancaster, Pa. Three other occupants were injured. The car was being driven carelessly and hit the side of the bridge, causing it to fall 25 feet to a railroad track below.

Latest Automobile Literature.

Driving a motor car with the right hand on the wheel and the left arm around the waist of a young woman constitutes negligence, acording to the ruling of Justice of the Peace A. Barnett, remarks the "San Francisco Bulletin." He gave judgment for $97.50 against G. W. Smith, jitney operator, in favor of May Goldsteiner because he had only one hand on the steering wheel when his machine collided with a car belonging to H. Allinger.

Smith's other arm was around Miss Bessie Goldsteiner, sister of Miss May.

Miss May Goldsteiner, who was siting in the back seat at the time of the accident, sued for $295 damages to her dress, eyes and nose as a result of the mishap.

How eleven automobiles were stolen in Paterson, N. J., within a few weeks was related recently to a detective sergeant of the Paterson Police Department, by George and Louis Ehlers, brothers, who are under arrest on charges of grand larceny. Some of the automobiles were taken from within a few yards of Paterson Police Headquarters.

According to the police, the brothers told him that, acting as "salesmen," they obtained orders from farmers for automobiles, and then stole machines which would fit the requirements. They overhauled and disguised the stolen cars and delivered them to their "customers." Seven of the automobiles have been recovered.

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

2189 **His Ford Car Creeps.**

From O. E. Lake, Massachusetts.—Will you kindly tell me what makes my Ford car creep when I start it after it has stood a while? By using very thin oil it works better, but I lose power, I find. I know of several that work the same way, but one I know of has to be jacked up until it gets warm. I suppose this is because some parts are worn. Can you tell me which ones? What do I need to remedy my trouble?

Reply.—There is a sector on the emergency brake lever that operates against a set screw linked to the clutch pedal. When the emergency brake is applied the clutch pedal is moved forward, disengaging the high-speed clutch. If this screw becomes worn the clutch will not be fully disengaged, and will give the creeping effect described. A slight turn down on this screw will overcome the trouble. A low-speed band that is adjusted too tightly or has loose or damaged lining, so as to cause a drag on the drum, will give the same trouble, as will a too tight adjustment of the high-speed clutch. It might be well to have the emergency brake bands renewed or adjusted, so that this creeping could not occur under any circumstance.

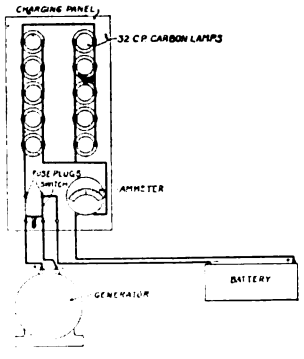
2190 **Engine Misses and Jumps.**

From R. Strehorn, Colorado.—Will you kindly give me your opinion what to do with my car with the following symptoms: I have a Chevrolet, model 490, which I have driven 9,000 miles. I am a machinist and take the best of care of my car. Of late I have had trouble with the motor missing on a speed of 8 to 12 miles per hour. I can throttle down to 4 miles on high and every cylinder will fire perfectly, but when I open the throttle the engine will miss and jump until I get up to 12 miles and then all the cylinders will fire perfectly. I have cleaned the cylinders of all carbon, reground the valves, put on a new breaker box, cleaned the carburetor, which is a Zenith, the same as when the car came from the factory. I have had some of the best auto

Digitized by Google

mechanics in Pueblo working on this car and it will not run any better. It only misses on a speed between 8 to 12 miles per hour. The car is equipped with Connecticut ignition. The battery is in perfect condition and the valve springs are all of the right tension and I have the best of compression and a new set of spark plugs.

Reply.—As you have checked up practically everything else, we would suggest that you try a size smaller choke tube in the carburetor with the next smaller size main gasoline jet, also. It may be necessary to do a little experimenting with different sized choke tubes and jets before perfect results are obtained.



2191 **Knocks and Backfires.**

From Charles C. Barron, Ohio.—I have an Alter, model C, 1916. It has been run 4,000 miles. The engine has never been cleaned at any garage. I cleaned it myself this spring and after that it seemed to run pretty well. Not long ago it would spit back through the carburetor more or less. Now it has quit that, but the cylinders leak some compression. It seems to pull better now and picks up speed pretty well, but it has a knock at 30 miles per hour or faster with spark lever partly and fully advanced; if retarded it cannot be heard or if running at a slower speed. Please let me know if you can give me any definite location of the knock and what to do for it; also the cause.

Reply. — This indicates loose connecting rod or wrist pin bearings. It would be well to have the carbon thoroughly cleaned out of the cylinders to make sure that the trouble does not lie there, and then, if the knocking continues, the trouble is quite certain to be found in the bearings and they should be taken up.

2192 **Charging the Battery.**

From Henry G. Buschman, Oklahoma.—I am running a Fairbanks-Morse engine of 80 horsepower in a light plant. I have a 6-cell, 12-volt storage battery. I am going to use it for ignition. Now what I would like to know is, can I charge this battery with this outfit? It is a 125-volt, 10-ampere com-

pound-wound direct-current generator. Please let me know if it can be done and how you would do it.

Reply.—The battery can be charged with the outfit described by connecting in accordance with the accompanying diagram. It will be necessary to use the bank of lamps shown on some similar resistance to control the flow of current, as the battery itself does not have sufficient resistance to regulate this. The ammeter is not absolutely necessary as each 32 c.p. lamp used will allow about 1 ampere to flow or each 16 c.p. lamp ½ ampere. The battery should be charged at 10 per cent. of its ampere hour capacity, when the electrolyte is between 1,150 and 1,250, and should be cut to 5 per cent. when the electrolyte reaches 1,250, that is, if a 100-hour battery is being charged, the initial rate would be 10 amperes, which would be reduced to 5 amperes when the electrolyte reached the specific gravity of 1,250.

2193 **That Loud "Puff."**

From R. I. Cougle, Illinois.—I have a Buick light six. At times a loud "puff" occurs. It sounds as if a petcock were open, but as there are no petcocks on my engine I can't seem to determine what the trouble is. I have traced it to the intake valve in the sixth cylinder. I thought maybe the manifold had something to do with it, but upon removing it I found it to be O. K. I ground the valve and it seems to set all right. I can stop this "puff" by either changing the oil daily or squirting oil on the valve spring. Now I find the first remedy pretty expensive and the latter I do not think is a good thing to do. I was told to use a heavier oil than I am using now (medium), but I cannot see why the puff would not occur in all the other valves, too, if the oil was too thin. I have had a new valve put in the cylinder. Any information you can give me on this subject will be greatly appreciated.

Reply.—The valve cage rests on a ground seat in the cylinder. Sometimes a small piece of carbon lodges on this seat and causes the trouble described. Make sure that the valve cage is perfectly ground in, also that the beveled brass ring on top of the cage is not out of place. We are not quite certain if you replaced the cage when the new valve was installed. If not, you will possibly find that the valve stem guide is worn and the cage will need renewing. We would also suggest that you check up the valve operating mechanism to see that there is sufficient clearance between the valve stem and the rocker arm during the entire period that the valve is supposed to be closed. Sometimes a cam is a little irregular and allows the valve to close, but slightly unseats it again during the time it should remain closed.

2194 **A Missing Cylinder.**

From Jos. F. Bird, Michigan.—I own a Model T Ford of 1914, and have been bothered at times with the second cylinder missing. I have tried changing plugs and units, have put on new timer and brush; also wiring and three new units, and still the trouble is there. The motor will work fine for three or four hours, and then it will start to miss again and keep it up for ten or fifteen minutes, then work smooth again. Do you think a new unit box would help any? What would you suggest?

Reply.—It is doubtful if the trouble is in the coil box. Sometimes the valve push rod becomes worn where the cam slides against it, and if the clearance between the valve stem and push rod is small, the push rod may turn around and the cam ride on a high spot at times. This takes up all the clearance, holds the valve off its seat, causing loss of compression with consequent skipping. This may be tested out by turning the push rod to different positions and making sure in each case that there is clearance when there should be. This trouble may also

Digitized by Google

be caused by a valve sticking in its guide. The valve stems and guides should be kept free from oil, otherwise they may become gummed and stick open occasionally. Does the vibrator for this cylinder operate when the skipping occurs? If not, the points may stick together or the vibrator make metallic contact with the end of the iron core of the coil and keep the points open.

2195 **Oil Leak.**

From Eugene L. Ferguson, Maine.—My Ford car leaks oil badly by the cam shaft into the timer so that it will skip. New washers stop it for only a short time. Will you please state through your paper if there is any other way of stopping the leak?

Reply. — The felts if properly installed with a metal washer in front should keep back the oil satisfactorily, and what leakage does occur should not cause any trouble as the timer ought always to have some oil in it; in fact there is an oiler provided on it for that purpose. The skipping may be due to a weak spring on the rotor or to dirt on the fiber parts that the roller runs on. The fiber should be carefully scraped clean and the spring replaced or its tension increased. The oil leak may be cut down by fastening a thin metal washer to the timing shaft just back of the timing gear cover. Oil attempting to pass through the opening of the cover will then collect on this washer and be thrown off into the case by centrifugal force.

2196 **Water for Batteries.**

From Albert F. Loebs, Michigan.—Will you please tell me if pure distilled water from an ordinary steam plant can be used in storage batteries safely? If not, why?

Reply.—We see no reason why water so distilled should not be admirable for the purpose. Rain water if not contaminated by dirt or dust is also suitable.

2197 **A Careless Inquiry.**

From H. J. Joens, Iowa.—Will you please tell me if it is a good plan to put a little lubricating oil in an automobile engine, and if so, how much?

Reply.—This question is too vague to answer intelligently. Sufficient oil should be carried in the crank case to have the end of the connecting rod dip into it slightly. Oil should not be put in the top of the cylinder, except when lack of oil on the cylinder wall is indicated by the engine turning over stiffly. Then two or three tablespoonfuls to each cylinder will answer. Putting oil in the gasoline, for the ordinary four-cycle automobile engine, is useless.

2198 **Battery Solution Level.**

From F. C. Barrios, Louisiana.—Would you be so kind as to explain to me an effective method which may be used to keep a storage battery from being damaged from the overflowing of solution in the same? This also destroys the wires, etc. Would you advise to use fluids that are sold to increase the mileage by putting same into the gasoline?

Reply.—For each battery there is a well-defined level up to which you should keep the electrolyte, and never raise it above that level. In some batteries the proper level is ½ inch above the plates; in some less and in some more. To test the level of a cell, unscrew the vent from its well, push a glass tube with both ends open straight down through the well and against the tops of the plates. Then close the top end of the tube with your thumb and remove the tube with the end still closed. The height of liquid in the tube will be equal to the height of the electrolyte level above the tops of the plates. Be sure and test the levels in all cells. As to the use of some fluid to increase the mileage of gasoline, such things have been advertised and are now on the market, but not having used any of them it would hardly be fair to endorse on condemn them.

2199 **Curiosity Inquiries.**

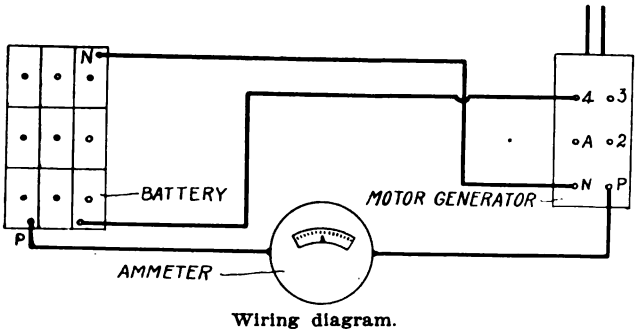
From G. H. Johnson, California.—1—Would it damage the magneto in any way to use a spark coil of twice the strength of the one on the Remy system, such as is used on the Buick, model 17, year 1909? If the low-tension Remy magneto described above would stand the strong coil mentioned, could the spark plug and interrupter points be run farther apart? 2—At what speed would a 4-foot propeller deliver its maximum propelling force, and about how many horsepower would be required to drive it? 3—Would a 4-foot aerial propeller drive a 2,000-pound automobile up a 35 per cent. grade if it were installed properly on the automobile?

Reply.—1—As the regular Remy coil is designed to take practically the entire output of the magneto and use it to the best advantage, it would not be possible to double the strength of the spark by the use of any other coil. 2—This would depend upon the pitch, width of blade, number of blades, and general design. The results obtained with different outfits vary so greatly that a practical test would be necessary if accurate information is desired. 3—There is none built at the present day that will do this.

2200 **His Inquiries.**

From H. P. Nichols, Connecticut.—1—I would like some information on the following points: In a recent article you speak of the fan wheel as a cooling factor. My car bothers on this line. Can you inform me at just what angle the blades should be set to give a maximum current of air on a Ford car? 2—There are on the market lamp regulators for Ford cars to prevent burning out of lamp. I have one and note that it seems to affect the running of the engine, when turned on for lamps much more than when direct running. Now can you inform me if this does not cause a loss of electric energy and what proportion? 3—Also in regard to various spark intensifiers on the Leyden jar principle. Also as a break and jump in secondary systems, do these arrangements accomplish much; and, if so, how much, and is there loss or waste of energy, and how much?

Reply.—The angle at which the fan blades should be set to give a maximum current of air, would vary as the speed of the engine varies, therefore, any angle would be best at only a certain engine speed. It is quite likely that the Ford company have determined the best angle for ordinary use, and it is doubtful if you will be able to improve upon it. However, if you desire to try it the blades may be easily bent and experimenting under actual conditions will



Digitized by Google

probably give you more practical information than any theoretical figure. If the fan belt does not slip, it is more likely that the trouble lies elsewhere, and we would suggest that you fill the cooling system with a strong solution of washing soda and water, run the engine several hours, and then wash out thoroughly with fresh water. 2—Any electrical device causes the loss of some energy. It is impossible to state how much energy is lost in any one of the many makes of regulators. If the engine does not run so well when the regulator is used, it is possible that current is being diverted from the induction coil, causing weak sparks at the plug. 3—We do not know of any successful spark intensifier, operating on the Leyden jar principle. The spark gap in the secondary circuit causes a higher voltage to be built up before the spark can jump, and, therefore, the spark is intensified. This causes ignition of charges that would not be ignited without such a gap. There is no waste of energy.

2201 **Installing Ammeters.**

From Fay Brothers, Louisiana.—We have a model 1916 (built the latter part of 1915) six-cylinder Chalmers motor car, also a 1910 model G. A. D. 30 horsepower White. The Chalmers was purchased with a self-starter, but on the White we installed a starter some years later. Both these cars have no ammeters to show the rate of charge or discharge. We have been requested to install ammeters on both cars and are sorry to say we cannot do it. We wrote to the Weston Instrument Co. and they claim we can do it, but have been unable to furnish directions to do so. Our electrician claims it cannot be done and we are still knocking at doors for help, for we are anxious to put the meters on the cars if it be possible. The starter on the Chalmers was furnished with the car by the company as part of the car. The one on the White was bought from the White company and installed later.

Reply.—We will have to ask you to give us the name of the manufacturer and the model of the

Wiring diagram.

starter system installed on the White car before we can answer this question, as we cannot be sure just what system was furnished you by the White company. The following, however, may apply in both cases. An ammeter that is specially built to stand the heavy current required to operate the starting motor may be procured from the Roller-Smith Company of 203 Broadway, New York, or Monadnock Building, Chicago. In the Entz system used on the Chalmers this may be attached to either the "P" or "N" wire leading from the battery to the generator which can probably be done without lengthening the wire more than five feet. If it is necessary to add more wire than this a new wire of larger diameter should be put in as otherwise the resistance may be too great to allow sufficient current to flow to operate the motor.

2202 **Motor "Bucks."**

From Reader, New Jersey.—I have a 1916 Ford car and have continuous trouble with the motor "bucking" on low throttle. I was able to run at from 4 to 5 miles per hour on low when new but of late I cannot throttle down to less than 10 miles without bucking and jerking. I have had everything done to it and spent enough money to buy a new motor and still it will not run without bucking. It has wonderful pulling power on hills and can make almost any grade on high. Then on a straight stretch I can't get over 30 miles an hour. I have driven it about 9,000 miles. I thought of getting new Never-Leak piston rings. Perhaps that would be the cause. Or could it be a faulty magneto? Replacing the piston rings is the only thing I have not tried. Can you offer any suggestion as to what might cause this trouble?

Reply.—It is possible that the magneto is weak. Running the engine on a set of dry cells will determine this. Or a slight change in the spark plug gap, either wider or narrower, may overcome the trouble. If the machine climbs hills well, Never-Leak piston rings will probably not help much. In many cases this trouble has been traced to wear in the throttle rod or in the carburetor casting through which this rod passes. Such wear allows air to enter the inlet manifold and makes it impossible to procure a good mixture when the throttle is nearly closed. To repair this, it will be necessary to ream out the holes and install a larger pin or purchase new parts. Leaky gaskets at the ends of the inlet manifold may likewise be responsible.

2203 **Tight Fitting Rims.**

From Robert Moore, North Carolina.—My car is an Overland 85, purchased this Spring. The wheels, 32x4, are fitted with Stonweld rims, and the difficulty is that the rims fit so unduly tight that an ordinary hammer has but little effect in endeavoring to get them on or off. I have had experience with clinchers, but they are a snap in comparison with these demountable rims. I wrote the Standard Welding Co. and they put my blame on the wheel maker. I suggested to the Overland dealer here, that the lugs or studs on the rim base be filed down a trifle, but he strongly advised against this method, saying the wheels, rims, etc., were all standard and therefore just right, and that all demountable rims are necessarily fitted quite snugly which required the use of a hammer (rubber one recommended) in putting on or taking off. This has never been my idea of what a demountable rim required, and rather than undergo again the fiendish trouble I had recently in changing, I determined to file off the studs on the rims. You understand I am not referring to putting on or removing a tire from its rim, but to putting on or removing the tire carrying rim on or off its wheel. I shall be greatly obliged if you can give me any help on this matter.

Reply.—This rim is supported at the back by a complete bevel ring and at the front by the several wedges. The studs do not carry any of the weight and usually do not touch the felloe of the wheel.

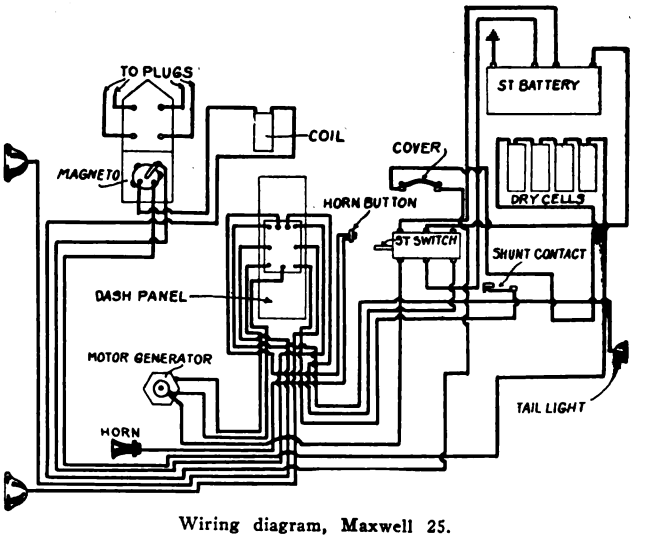
Digitized by Google

Their chief use is to keep a slight space between the rim and the felloe so that the wedges may easily be entered; except the one at the valve stem, which, of course, keeps the rim from creeping and breaking off the valve stem. Certainly, a demountable rim that must be put on or taken off with a hammer, even a rubber hammer, falls far short of its purpose, and we would, by all means, advise that you file off the studs so there will be no difficulty experienced in making the change.

2204 Can't Keep the Battery Charged.

From J. B. Belcher, Virginia.—I would be glad if you can give me some information on the following: I drive a Maxwell 1917 model touring car, equipped with the Prest-O-Lite starting and lighting system, and cannot keep the battery charged. It will go down once every month. The generator shows charging all the time when the car is making 15 miles an hour and over in high gear. Have had the wiring gone over and it seems to be in perfect condition. The battery is kept in water at the proper point, yet it runs down and will not turn the motor over after a full charge for more than two weeks. The motor is very hard to start and has most of the time to be cranked. I have a Stromberg carburetor on the car, which is in perfect condition. Any information you can give me will be appreciated.

Reply.—We are not familiar with the Prest-O-Lite starting and lighting system. The Simms-Huff system with a Prest-O battery is the regular equipment for this car. The fact that the motor starts very hard may account for the battery becoming quickly discharged. Other Maxwell owners have found that the engine may be more readily started with less drain on the battery if the starter pedal is released when the first half revolution of the engine is completed. If the starting motor is not thrown out of mesh the instant the first explosion occurs, it causes considerable drag on the engine, slowing down the speed of the crank shaft so much that the second spark is too weak to ignite the charge. The result is that the engine is cranked, one explosion occurs, the engine turns a few revolutions without an explosion, and then one more explosion occurs with the same result. Occasionally, the first explosion will develop sufficient speed to give a good spark in the cylinder following, and the engine starts. Otherwise, an excessive amount of current is used. With a little practice you will learn to anticipate the first explosion and release the starting pedal so that the motor gear will be slid out of mesh just as the explosion occurs. The engine will then turn freely and start without difficulty. Although the generator charges the battery at speeds above 15 miles an hour, it may not charge at a high enough rate. You might check this up with other Maxwell cars, and if the rate is low, clean the commutator with No. 00 sand paper, and if then necessary have the regulator adjusted.



2205 Storage Battery Power.

From Barber, Johnson & Co., South Dakota.—Will you kindly tell us through your magazine why each cell of a storage battery has an energy of only 2 volts approximately? Why is it not possible or practical to build a six, eight or ten volt cell on even a sixty or one hundred ten volt cell?

Reply.—In a storage battery electricity is produced by chemical action. When two lead plates are immersed in a solution of sulphuric acid of 1,300 specific gravity, an electrical pressure of practically 2.5 volts is generated. By increasing the strength of the acid, a slightly greater pressure may be generated, but the plates would be attacked and quickly wear out. Also, the battery would rapidly discharge itself when not in use. It has been found that a battery using an electrolyte of 1,200 to 1,215 specific gravity gives the longest life, holds its charge best, and is most satisfactory in every way, except that the voltage is slightly lower and a greater quantity of acid is needed. The 1,300 specific gravity electrolyte is used in automobile batteries at the sacrifice of the life of the battery in order to decrease its bulk. Other types of batteries have been built which give a greater voltage than the lead battery, but the action of the electrolyte is so violent that they fast destroy themselves and, therefore, are not a commercial success. There are other batteries in general use that are preferable to the lead battery for some purposes because they will stand greater abuse, although the voltage generated in a single cell is only about half that of the lead cell. So far there has been discovered no combination of chemicals and metals that will give a high voltage with a reasonable length of life.

2206 Wiring of the Maxwell.

From J. Belanger, Massachusetts.—Will you please tell me how to wire a Maxwell car equipped with a Simms magneto and Simms generator?

Wiring diagram, Maxwell 25.

Model of the car is No. 25, 1916. I will greatly appreciate it.

Reply.—The accompanying wiring diagram is what you wish. This is the standard equipment for Maxwell cars. The combination cut-out and regulator is mounted on the rear of the dash panel carrying the ammeter and switch.

2207 Valve Location.

From Andrew B. Fennewald, Missouri.—Are valves in the head motors better than other kinds and in what respect? Have they any disadvantages? Are they more powerful?

Reply.—The location of the valves is a matter of choice on the part of the designer of the motor. As

Digitized by Google

far as we know no one can tell which location is the better. If some one were possessed of this knowledge valves would be uniformly located. Some engineers prefer valves in the head and others prefer them on one side. The main consideration of valve design and location is that the gases be admitted and discharged from the cylinders as quickly as possible in order that the speed of the gas flow will not be impeded and cause back pressure.

In Descending Hills.

From Carl Goodenough, Littleton, New Hampshire.—In answer to Mr. Sears regarding high to second shift in the Overland 83. On a level road, slow down to five miles an hour and then shift smartly. On a hill, throw out the clutch and drop to a ten or twelve mile speed; then press the accelerator slightly, and simultaneously put the shifting lever into second speed. This double action is confusing at first, but it is entirely practicable. Try to imagine the right hand and right foot as one member, working together. I would say, in passing, that the steeper the hill the less one needs to accelerate, since the natural slowing of the car compensates for a lower engine speed. If the hill is very steep, don't be foolish; shift at the bottom.

Is Mr. Larkin in the Audience?

From F. H. Schultz, Kansas.—I would like to ask John B. Larkin of Pennsylvania, to give through your paper a little more information in regard to grease leaking through the Ford rear axle. He says to place a felt washer in ahead of the bearing, then put a new washer between the bearing and wheel. Is it necessary to use a metal washer in between the bearing and felt washer to keep the bearing from cutting out the felt washer, or will the felt wear all right without a metal washer? I have been a little afraid to try the felt washer for fear it might cut out or clog the bearing so it would not turn. I have had all kinds of grief with gears leaking at the axle, and would like some way to stop it.

New Place to Carry Tools.

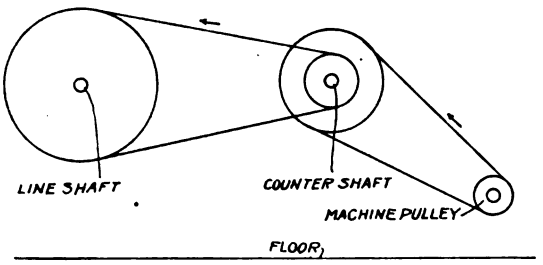
From John C. McCandless, M. D., Illinois.—While physicians frequently find it necessary to explore cavities for foreign substances, it does not seem fair that tire and tube manufacturers should leave worn out iron tools inside of rubber tubes, and sell the job lot for new goods, as the following will explain: After running a new 36x5 tire and tube for about 800 miles, the tire went flat and on removal I found a half-inch cut in the tube, but no evidence of any injury to the tire in any way. I inserted a new tube in the tire and proceeded on my way. The following day I put a patch over the half-inch cut in tube without ascertaining the cause of the cut of the day previous. Had occasion soon to use this same tube in another tire, and after running about 200 miles, I found the tire was slowly getting slack. On removal, the patch was discovered to be leaking, and after repatching and all the handling I had given this tube, I felt a hard, rod-like substance inside of it. I then pushed the end of this antiquated iron tool through the body of the rubber tube and found it to be seven inches long, slightly bent. Lest some readers of your valuable journal suspect this long hard substance, found in the bowels of a rubber tube, be a petrified tapeworm, I am forwarding the same to editor in hopes that he may be able to classify this archaic specimen. The tube was manufactured in Ohio, and was used on the rear wheel for 1,000 miles in this pregnant condition. A question naturally arises as to whether this object kept looping the loop, regardless at what speed the wheel was revolving, or did it pursue treadmill tactics? In either case it would keep in contact with the outer side of the closed circle. Tools generally accompany automobiles and accessories for purposes of repair, but this one for purposes of destruction.

Note by the Editor.—As the doctor has complimented us by forwarding the full grown bacteria, not for publication, but as a guarantee of good faith, for our identification and classification, we hasten to report with considerable pride. To tell the truth, we always had an eye to being a physician. After having made a close analysis, we have decided it is of the strepto-pneumoccoccus order or group, somewhat flattened, elongated and water-logged. It probably gave the tire tube chronic sinusitis, but could have readily been expelled by the use of forceps having the corpus callosum curved forward. The doctor naturally seems to be of the opinion that it was carelessly left there after the operation by the tire maker, after the manner of—well, never mind—but we can assure him it is an artificial growth due to infection. One of our matter-of-fact assistants—a regular Grandgrind, in fact, who has no imagination whatever—says it is a screwdriver or some other tool carelessly left in the tube by a workman, and carried there so long that it has been flattened and bent all out of its pristine semblance. But he is not scientific and does not understand saprophyte life.

THE LINE SHAFT.

Its Connections, Operation and What It Requires For Certain Work.

From J. F. Springer, New York.—The line shaft is an important item in connection with the transmission of power from an engine or motor to various parts of the shop. Before considering where it should be located, let us look into the question of its size. We may easily buy a piece of shafting of too small a diameter and find ourselves involved in difficulties later on. On the other hand, if we get shafting too large, we become involved in a needless extra investment to say nothing of other matters. It is possible to determine in advance the diameter needed to give the necessary strength and rigidity and yet not involve us in buying steel for which we have no use. We must, however, determine the total horsepower we are going to transmit by the shaft and also the number of rotations per minute the shaft is to have when transmitting that horsepower.



Suppose now that the horsepower is to be 8; and that we have determined that, when connected up and operating at full load, the engine will rotate the shaft at the speed of 140 rotations per minute. We want to find out just what diameter of shafting is properly required for the work. It is assumed that cold rolled steel is the material of the shafting and that the hangers are reasonably close together. What we have to do in order to get the shaft diameter is simply to multiply the horsepower by 55, then

Digitized by Google

divide by the rotations and finally take the cube root of the result. This cube root will be the answer required.

Take the case we have supposed. The horsepower is 8. We multiply by 55 and get 440. The revolutions per minute are 140. We divide and get 3.143. Our final job is to take the cube root of this last number. We may have to look up our old arithmetic in order to find out how to take the cube root. Or, we may get some one to do it, if we feel unequal to the task. It is only a few minutes' work for one who knows how. We get for the cube root in the present case, 1.464. We learn then that our line shaft should have a diameter a trifle less than 1 29/64 inches. This will probably be an odd size; so we select something a little higher—not something a little lower—and fix upon 1 15/32 or 1½ inches. This is much better than guessing. It gives a practical certainty. If we should be compelled to guess, the only way is, of course, to guess a size too big. This wastes money, not only on the shafting itself, but on other items.

A line shaft may be driven from one end. Or, it may be driven from a central point. Other things being the same, it is undoubtedly better to effect the drive at a point midway between the ends. This may or may not be convenient, as it may require the

Line shaft along one side of the shop with machines along opposite side.

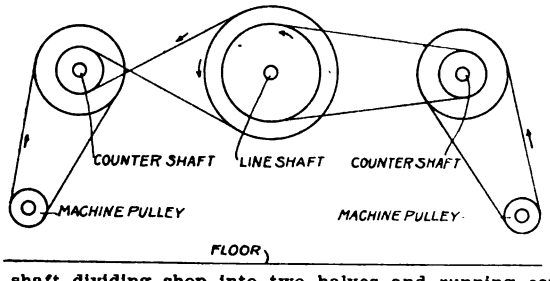
engine to be given some undesirable location in or about the shop. Better operation may be counted on, however, if the shaft can be driven at its center. The shorter a shaft, the greater its ability to resist the twisting effect of the drive. With a central drive we have in effect substituted two short shafts for one long one. All the machines will then be near the driving point.

In either case, whether the driving point is at one end or in the middle, the heavier machines should be placed closer to the drive than the lighter ones. In an ordinary repair shop, the metal turning lathe may be the machine requiring the most horsepower for its operation. If so, set it as close to the driving point on the shaft as can well be done, rather than further along the shaft. An advantage of driving the shaft from a midway point is that we double the number of positions close to the drive.

It is not at all wrong to locate the line shaft near to one side wall; but it is customary to set it nearer the half-way line between the two walls paralleling the shaft. If there are only a few machines and the shop is long enough to accommodate them all in one row, then the line shaft may be put along one side of the shop. On the other hand, if the shop is not so long, but has a good width, it may seem more desirable to locate the shaft half way between longitudinal walls and use two rows of machines—one row along one side of the shop and the other along the other side. The line shaft would thus be between the two rows.

It is a matter of very great importance that the line shaft, when suspended in the hangers, shall be absolutely straight. If it is stressed a trifle to one side, we may readily discover this fact by attempting to rotate the shaft with the hands. If right, the shaft should turn easily. There should be no places in the turn that are hard to get by. The shaft should turn easily and evenly all the way round. Do not let anything induce you to let matters go, if they are not precisely right.

The line shaft should be very rigid in its position, as there will be stresses on it from the machines or the counter shafts, these stresses tending to shift it to one side. To secure the proper rigidity there should be enough bearings along the length of the shaft. These should be well distributed. Seven feet is a good interval between bearings. On the line shaft will ordinarily be a number of pulleys, receiving and transmitting power. At the point where the shaft is driven will be a pulley connected with the engine by means of a belt. This pulley receives power on its rim and transmits it thence through its hub or a clutch to the shaft. The shaft will ordinarily transmit its power, thus obtained, through the hub of another pulley. This pulley in turn transmits the power from its hub to its rim and the rim to a belt running off to some other pulley. A moment's consideration will make it clear that the belts stress the shaft to one side. It is important, then, in order to minimize bending the shaft between bearings, to locate pulleys as close to bearings as possible. There will then be not so much leverage exerted on the shaft by the pull of the belt.



There are other ways of transmitting rotational power from one shaft to another than by using a belt; but this is the one most in use. The belt may be of leather or of other special materials. If of leather, the best belting is made from oak-tanned hides. These should, it appears, have been curried with the use of cod oil and simple tallow. A first-rate belt of high-class leather properly used will last twenty or thirty years or even longer. There are two sides to leather belting—the side on which the hair grew and the side that was next the flesh. The hair side shows more or less of a grain. This side should be put next to the pulley rim. There are several reasons for this. When a belt is bent round a pulley, the inside of the curve is shorter than the outside. That is, the material is crowded together on the inside and stretched on the outside. Investigation has made it pretty clear that the hair side is weaker than the flesh side. It is, for this reason, thought best to put the stronger (i. e., the flesh) side on the outside of the curve and thus provide strength to take care of the stretching stress. The hair side is the smoother of the two and will, when placed so as to be on the inside of the curve, cling to or hug the pulley rim with greater effectiveness.

Belts are made of a single thickness of leather, and also of double thickness. In the latter case, the two layers may be cemented together. There are thicker beltings, but they will scarcely need to be considered by us. Naturally, we shall have to use a belt of proper strength in order to get the amount of power into, say, a turning lathe that we need for proper operation. The faster a belt runs the more

Digitized by Google

power we may transmit with a belt of given strength. It will not, perhaps, be advisable for us to go into difficult considerations. It will be sufficient for our purposes to have a good general rule. An authority on the subject states in effect that a single-thickness belt 1 inch wide may be used to transmit 1 horsepower, provided the belt is run at the speed of 1,000 feet per minute. We may use the slower speed of 600 feet per minute and still get 1 horsepower out of 1 inch width, if we use double thickness. If we have belts 1½, 2, 2½ inches broad or broader, we get the horsepower that may be transmitted by making proportionate allowances. Thus, a single-thickness belt 1½ inches wide, running at 1,000 feet per minute, will transmit 1½ horsepower; a 2-inch belt, 2 horsepower, and so on. If the belting is of double thickness and the speed is 600 feet per minute, then for 1½, 2, 2½, etc., inch belts, we calculate that we can transmit 1½, 2, 2½, etc., horsepower. That is to say, with either type of belt, we can transmit horsepower in exact proportion to the width of the belt. This is quite important, because it enables us to tell what sizes of belting to use to run the various machines.

From line-shaft pulley to counter-shaft pulley, we are apt to have a slower belt than between the pulleys on counter shaft and machine. However, the horsepower is just the same, or very nearly the same. We will, accordingly, need either a thicker or a wider belt for the former case than for the latter. The reason is this, the slower the speed the less horsepower may be transmissible with a given thickness and width of belt. And this operates proportionally. That is to say, for example, a 2-inch, single-thickness belt running at 500 feet per minute will transmit half the horsepower transmitted by the same belt running at 1,000 feet. The same 2-inch belt running at 1,600 feet would transmit 1.6 times as much horsepower.

Line shaft dividing shop into two halves and running countershafts and machines on both sides of the shop.

Suppose, now, we have a line shaft rotating at 140 turns per minute and a pulley on this shaft whose circumference is 4 feet. If there is no slippage of the belt on the pulley, we shall get a belt speed of $140 \times 4 = 560$ feet per minute. If we deduct 20 per cent. for slippage, we get 448 feet per minute as a fair determination of the actual speed. A 1-inch single-thickness belt running on this pulley can not, therefore, be expected to transmit 1 horsepower, as it would do if running at 1,000 feet. It may, in the case where the speed is 448, be depended upon to transmit 448/1000 of 1 horsepower, that is, 0.448 hp. If the machine which is to be operated is going to require, say, 2½ hp., then we will have to broaden the belt in case we stick to the single thickness. We broaden it, but how much? Every inch of width gives us 0.448 hp.; so we shall require as many inches as 0.448 is contained in 2.5. That is, 5.6 inches. This is pretty wide; so perhaps we would better consider the double-thickness belting. With it, a 1-inch width gives 1 hp. with 600 feet of speed. Consequently, with 448 feet of speed, we shall get only 448/600 hp.—that is, 0.747 hp. To get 2.5 hp., we shall need as many inches of breadth as 0.747 is contained in 2.5—that is, 3.3 inches. This, then, is the width required of double-thickness belt to transmit 2.5 hp. from the line shaft to the counter shaft. We ought to allow something over for the reason that some horsepower is really lost when slippage takes place. And for the same reason, there will be an additional loss between the counter shaft and the machine. If we want to get the full 2.5 hp. at the machine, a 4-inch belt should probably be selected.

We can reduce the belt width, and consequently the pulley width, in two ways, without adding to the thickness. First, we may operate the line shaft at a higher rate than 140 turns per minute. Second, we may increase the diameter of the line shaft pulley. If we double the pulley diameter, we double the speed of its rim, and also the rate of movement of the belt. This would result in the 4-inch belt being able to transmit double the horsepower. So, we are able to split the belt and get our 2.5 hp. by 2 inches of width instead of 4.

The joining of the ends of the belt is an important matter. It is probable that splicing and cementing, though recommended by high authority, will hardly be practicable. We turn then to other methods. There are three (1) Lacing, (2) gluing, and (3) using metal hooks or links. The importance of having a proper joint is perhaps not recognized as fully as it should be. The joint should be just as strong as the belt. Then it should be quite smooth on the pulley side. A want of smoothness seems to prevent proper adhesion between belt and pulley by breaking up the tendency to a vacuum. Then the completed joint must not be heavy, as this would create an unbalanced condition.

(To be continued.)

OVERHEATING ENGINES.

Common in Hot Weather But They May Be Avoided With Proper Care.

From H. Clifford Brokaw, New York Y. M. C. A. School.—The automobile engine will heat up too quickly in hot weather, just as an individual will. No, Percy, I did not say overeat; though if you let the engine gorge itself too long on motor fodder, it will help to overheat as well as overeat. There are a variety of reasons for the overheating, which it is well for the novice to understand.

Those who have found it necessary during the winter to cover the radiator and take off the fan belt and do other things to keep the engine hot enough to run smoothly and with the proper vaporization and firing, may find now that they are having as much or more trouble in keeping the engine cool enough to run properly.

Generally speaking, the nearer to the boiling point we can run the engine without actually having the water boil and steam away, the more efficient it will be. Some engines, in fact, develop much less than the maximum horse power because they are too well cooled, and yet this is the time that we get a great

Digitized by Google

many complaints about the water boiling in the radiator and the engine overheating.

This would not occur if everything were working as the designer intended it should. During cold weather the man who drove with a retarded spark used up more gasoline than was necessary, but he was not bothered with overheating. When the mercury goes up he finds that his engine overheats and gives him trouble. He has not changed his manner of driving and cannot understand why there should be trouble.

Driving the engine at high speed with the spark retarded is one very good way of overheating the engine. As a matter of fact, the battery ignition systems which are now coming more into use require considerable manipulation of the spark control lever, and the tendency is, because the engine knocks at low speed, to leave the lever partly retarded, instead of advancing it, when a higher speed is reached.

With the magneto it is the general practice to advance the lever to three-fourths or seven-eighths of the full range right after the engine is started and leave it there for practically all work. except very high speeds. This may be done largely with such a system, because the nature of the spark given by the magneto changes somewhat with the speed of the engine and the equivalent of an automatic advance and retard of the spark occurs with the variation of the speed of the motor. With the battery system, however, there is very little change in the nature of the spark effected by the engine speed.

A frequent cause of chronic overheating may be traced to sediment in the radiator which cuts off free radiation of the heat. This usually may be removed by the use of a saturated solution of washing soda and water. About this time of the year it would be well to fill the cooling system with a solution of this sort and run the engine for several hours and then drain it off and refill the system with clean water. If in the system used a pump is employed, one should disconnect the upper hose from the radiator and run the engine to pump the solution out of the system. At the same time water from a hose or other source should be fed into the top of the radiator as fast as it is pumped out, and thus flush the entire system.

Where the thermosyphon system is used, which does not employ a pump, this, of course, cannot be done, but one should remove both upper and lower hose connections after running the engine with the solution and wash it out with fresh water as well as possible. A hose inserted in the upper connection probably would force all the solution out with any sediment collected, and the same process with the radiator ought to clean it out.

Fan belts are more likely to get out of order in hot weather than in cold weather; perhaps this is because the engine throws oil or grease more readily when it is warm. Belts should have grease enough to keep them soft and pliable, of course, but too much causes slipping. They should be wiped free of oil occasionally. There is always a belt adjustment and this should be adjusted so that there is sufficient tension to drive the fan at all engine speeds.

Some engines have the spokes of the fly wheel shaped to form a fan and where this is the case the oil pan and hood should be kept tight so that air will be drawn through the radiator rather than through other openings. If the radiator is not kept free from oil the outside passages will very quickly collect dust, which will prevent a free flow of air and cut off radiating surface, which also occurs when the front of the radiator is smeared too thickly with paint.

Pumps do wear out, but this is one of the last places to look for trouble. The action of the pump may be determined usually by removing the radiator filler cap when the engine is running and noting whether the water is circulating, but if a baffle plate is placed in the filler opening, it cannot be seen, and a test may be made in the same manner in which the cleaning solution is washed out, namely, by removing the top hose from the radiator and running the engine, while supplying water through the filler opening.

With the thermosyphon system there is very little pressure generated and a slight obstruction will stop the flow of water. Therefore it is more necessary to keep the system free from sediment and to see that the gaskets at the joints are made with circular openings of the right sizes so as not to obstruct the flow of water. Likewise water must be kept above the top hose of the radiator in order to have any circulation in this type of cooling system.

Another cause of overheating which it has been found very difficult to locate, comes from carelessness in stretching the hose over the pipe. In doing this sometimes the inner lining of the hose is loosened and folds back, covering the opening of the pipe, so that water does not flow freely. It looks all right from the outside, but an examination of the inside will show that it is almost entirely clogged at the end. Also the lining of the hose will often loosen up and pieces will lodge where they cut off the circulation.

Keep the engine free from carbon and keep the valve push rods adjusted close, have the mixture as lean as possible, and be sure the exhaust from the muffler is free. Taking care of these things and seeing that the other things mentioned are all right, will prevent most of the overheating which troubles the novice, if, indeed, not all of it.

They are things which should not be trusted entirely to chauffeur or garage man, but the owner should learn how to take care of each himself; then if he wants to hire it done he will know if it is being done according to his orders and will recognize the symptoms when anything goes wrong. It may take a little time and get one's hands somewhat soiled, but it pays in the long run, not alone in the saving of labor, but in the absence of annoyance when out on a trip. It is far from pleasant to have to stop along a hot roadside to make repairs which should have been done in the garage, let alone the delay and consequent upsetting of schedule. Therefore, it behooves the owner to look after these things before starting out and to learn his car so well that he will anticipate trouble and by removing causes save time and money.

It has been well said that there is one set of bearing surfaces on a car which should never be oiled—the brakes. This is not strictly true, as a squeaking brake must be oiled, but with caution. Use castor oil in moderation until the squeak is stopped.

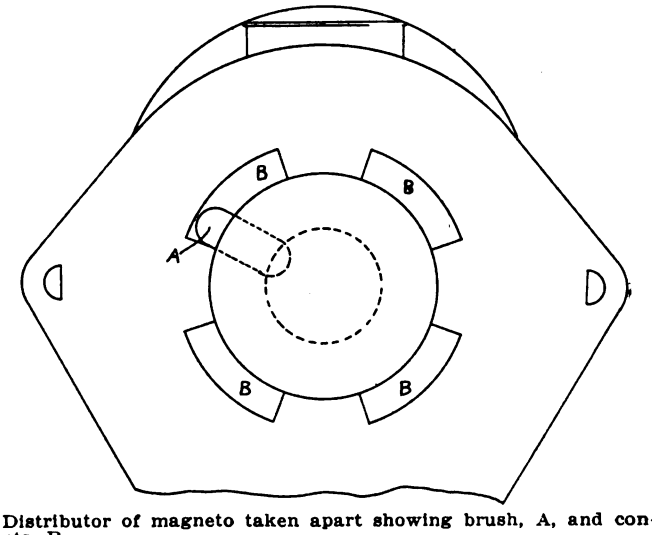
STARTING THE CAR.

A Few Suggestions That May Prove Useful in Case of Trouble.

If your car fails to start do not get red in the face or do anything at haphazard. There is a cause for everything and there is a remedy for everything. But if your car fails to start, you will naturally first try flooding the carburetor, make sure that the switch is in the proper position, open the petcocks and closing the eyes to guard them against any particles of dirt being thrown up, blow down each petcock, with the lips just a little removed from actual contact. The object of this is that, so far as carburetion is concerned, the failure of the engine to start up may be due either to a mixture which is much too rich or to one which is too weak. If the cylinders are charged with too rich a mixture, this action will thin it out: allow the petcocks to remain open for, say, half a minute or so.

By the end of this time it may be assumed that if the mixture were too strong it will now be quite weak, as the gas will rise up (it does not rise very high) sufficiently to leave a weakened mixture. Now put about six drops of petrol into each petcock and again allow them to remain open for a bare half-minute. Close them and have another swing. If the difficulty has been one of bad carburetion the engine will probably start now, and when once running the trouble is not likely to be very manifest.

It is rather a difficult matter to lay down any didactic instructions as to tuning up or adjusting a carburetor which is out of adjustment, as there are so many of them, and they vary considerably, not only in their complaint but also in the method of adjustment. In fact, it would require a small book for this subject alone, if one were to give a full series of instructions in the art of adjustment and the work of tuning up the various standard carburetors on the market.



If the foregoing simple instructions have not proved successful in solving the problem, which seems to appertain to carburetion, then one may be looking round for indications of trouble further afield. Just occasionally it may be that a continual flooding takes place, and if this is so it is probable that a slight leak has occurred in the float, so that some gasoline has got inside it, and it does not rise quickly enough to actuate the little ball governors which shut off the needle valve.

Yet, again, it may be that the jet is choked with a minute particle of dirt, or partially choked, so that there is not a quick enough flow of gasoline, in which case it is, of course, necessary to remove the jet and clean it. Sometimes the jet itself may be found to be quite clear, but the passage from the float chamber to the jet may, perchance, be blocked up: there is usually a little screwed plug which can be readily removed to make sure this is not the trouble. On the other hand, the filter may be choked up, and this is a trouble which can be simply remedied. Yet, again, even the gasoline pipe itself from the tank may have got choked or the tap in some way have been turned off, either of which complaints can soon be detected.

How Trouble May Be Hidden.

One of the most extraordinary cases of trouble in locating a shortage of gasoline supply to the carburetor which has ever come under the writer's notice was due to some graphite which had found its way into the little air vent of the cap of the gasoline tank, which, of course, was a gravity-fed one. This had hardened, and as the cap was provided with a good washer the tank had thus become air-tight, so that when a certain quantity of gasoline had flowed out the partial vacuum in the tank arrested further flow. All the various defects previously alluded to had been carefully gone through by the driver, and he and his assistant were naturally sure of a ready flow of gasoline when the copper pipe itself from the tank to the carburetor had been finally proved to be free. They were greatly astonished when, on turning on the gasoline once again, it was found that the flow of spirit was still in some extraordinary way much too slow and insufficient for the needs of the engine.

As a final resource the then-unknown-to-be faulty cap of the tank was removed to make certain that

Distributor of magneto taken apart showing brush, A, and contacts, B.

the gasoline, which was known to have been in the tank, had not been stolen. All was found to be well, and on trying once more the flow of gasoline was suddenly found to be restored to its normal conditions. The coincidence set the driver and other folk thinking, and then the solution of the problem was quickly found. This fact is not mentioned as a matter in any way likely to crop up, but it serves its purpose in pointing out that, if one finds the flow of gasoline is not free, it is not always sufficient merely to cleanse the filter.

For ordinary starting-up purposes in those cars in which it is necessary to flood the carburetor, it is well to remember that slight flooding usually produces easier starting than excessive flooding; obviously, also, it is less wasteful, so that the point should be remembered. If it is found that the engine still refuses, then it is safe to assume that the trouble is due to ignition rather than to the question of carburetion.

Simple Ignition Difficulties.

If, after the carburetor has been duly doctored, the car is still obstinate, as a first step remove the main earth wire from the magneto, and—have another swing. If this proves successful it is reasonable to assume that there is something faulty with the switch itself, or that there is a shortage in the switch wiring. If so desired, the car can now be run

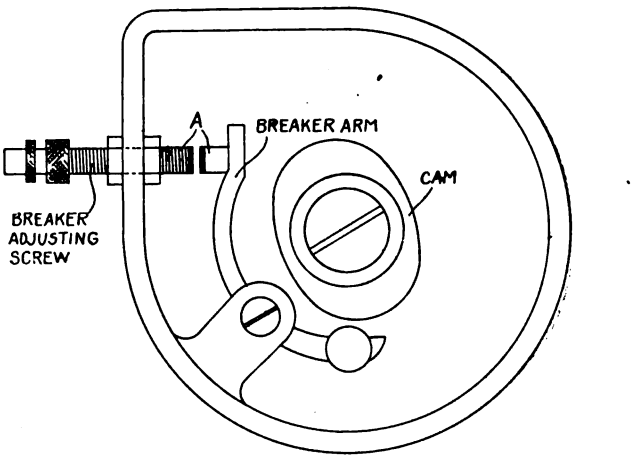
Digitized by Google

just as ordinarily, except that one has not got a switch in operation, so that the engine must either be stopped by means of the throttle or the wire replaced and the engine stopped through the medium of the switch.

It is perhaps well to rule out of court a common fallacy: absolutely no harm will accrue to the magneto by using it with the main "earth" wire (it should be actually "frame" or switch wire) detached. It is just worth recording that if one finds the refusal to start up to be due to some part of the engine's electrical appurtenances, one should try the switch in the off position—in other words, in exactly the opposite position to that which is used ordinarily for starting up. It may just chance that there is some defect in the switch itself. Admittedly, it is not often that this is the case, but the writer well remembers the great consternation of a certain well-known motorist, who had spent a great time in trying to start up his engine, and after pooh-poohing the idea, reluctantly allowed a friend to swing it with the switch in the off position. At the first pull the engine started quite easily, but as the owner's only comment was far more expressive than useful, it is not advisable to record it. However, the fact itself remains that just on an odd occasion the switch may so misbehave itself as to be "on" when it is in the off position and vice versa. If these simple little first-aid remedies are not effective then one must seek a little further afield for the trouble.

Further Electrical Adjustments.

Any continued inability to start when once traced to some portion of the electrical appliances must then be sought for in other directions. First of all have a look around at all the wires to see that the terminals are right, the connections good, and the insulation not broken anywhere in a position in which a shortage could occur.



A plug may now be examined and, if found to be dirty, that is to say, internally, sooty or very oily, it is reasonable to assume that the others are in the same condition. Therefore, take them out and clean them, for which purpose a small quantity of gasoline may be employed to rinse them in, although, of course, one must be careful as to its after-disposal.

En passant, it should be mentioned that one should never throw gasoline down a water drain, and if it is necessary to throw the spirit away do not so dispose of it en masse, but sprinkle it about in small quantities over a good area, so that it will quickly evaporate. If by chance someone should throw a light down, it is only the few spots in question which will fire, and consequently no damage is done.

About the Plug Gap.

There is usually too great a tendency to have a wide gap between the electrodes of the plugs; the best working distance between the points of a plug is (very roughly) the thickness of a fairly stout visiting card. Either more or less is, generally speaking, conducive to bad running, and is also detrimental to the ignition system itself. Also note if the tips are clean, if not they may be cleaned by the use of a very fine file, if one has one, if not one can generally use the blade of a penknife and carefully push it through, which is usually a fairly satisfactory means of doing the work. If the width of the gap is found to be too great the prong of the electrode should be very gently tapped over with a good-sized key, or carefully bent, as may seem more easy to the person concerned in the adjustment. Many motorists are inclined to think that a wide gap in the plug means a big fat spark, and therefore a higher rate of flame propagation, and consequently more power. It must be remembered, however, that for other purposes it is necessary to provide a safety gap in the magneto itself, and if the width between the electrodes is too great, then, owing to the compression of the gas in the cylinder, the spark will refuse to jump the plug gap and select the one in the safety gap in the magneto itself, for preference.

Also remember, therefore, that because the spark jumps quite readily across the gap when the plug is laid on the top of the engine, it by no means follows that it will do so when screwed down in position, as the gaseous pressure is greatly increased, and the greater the pressure the greater the current

Contact breaker of a magneto—make and break, A, must be kept properly adjusted.

requisite to jump a given distance between the electrodes. This fact may be more completely grasped when it is stated that the actual safety gap in the magneto itself, where there is no air compression, is usually set 12 or 13 times as wide as the width of a plug gap.

If the plug is really badly sooted up, so that ordinary rinsing in gasoline does not appear to clean it, then the center electrode of the plug itself may easily be removed so that both portions may be cleansed separately.

Cleaning the Distributor.

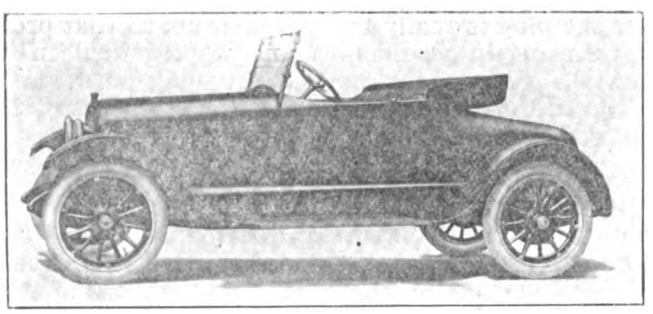
In the upper little cover-case at the end of the magneto is to be found the distributor, and if the aforementioned efforts have failed, then the covering disc should be taken off and the distributor brush, A, inspected, and if necessary cleaned. Sometimes a little oil and carbon dust may have combined to make a "shorting film," which should be carefully wiped out with a piece of clean rag, and this may be just dipped in gasoline if one takes care not to use too much gasoline, and to give it time to evaporate before turning the engine again.

The Contact Breaker.

If irregular firing should occur, it is practically certain that it is due to faulty working of the contact breaker. This is the lower of two little chambers at the end of the magneto, and the cover can

Digitized by Google

be easily removed. First of all see that the little center screw is quite tight, and also that the steel segments are rigid; also note that the two platinum contacts are in good condition—not dirty and jagged.



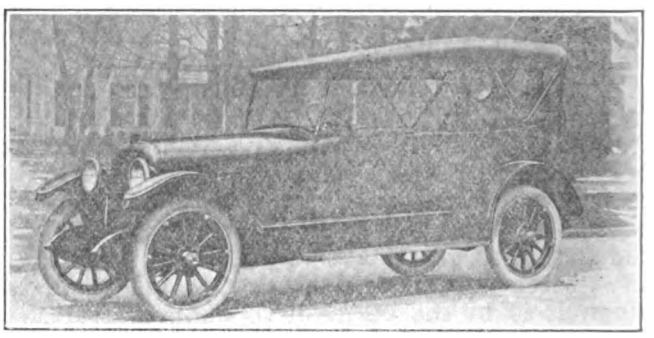
Here, again, any oil or grease should be carefully removed, and if the contact points are uneven or dirty they must be carefully cleaned or adjusted. When the small bell crank lever is at its maximum depression, then the distance between the two points should be exactly the same as in the case of the spark plug gap: roughly, the distance of a thick visiting card, if no better means of gauging the dimension is available.

If these first-aid instructions still fail to make the engine start up, then it is advisable for the average motorist to seek the aid of someone who specializes in motor work, unless by study, experience, or natural ability he feels competent to go into such questions as the correct setting of the magneto, etc. In any case, even to the fairly expert motorist, further dismantling of the magneto is not to be recommended; put more bluntly, though with more truth, it should, in fact, be avoided, as adjustments beyond the nature of those already alluded to require the return of the magneto to the manufacturers.

THE ROSS CAR.

Important Changes in the Organization of the Company and in the Motor.

Two radical changes have recently taken place in the affairs of the Ross Automobile Company, Detroit. One is a change of management, the other a change of motor. These changes will mean a new source of energy for both company and car. If the saying is true, and we believe it is, that any institution becomes as big as the man at the head of it, the Ross Automobile Company is slated for a prominent place in the automobile industry. The company has planned an aggressive campaign to put the Ross in the front rank of high grade cars. The present strong and well-rounded organization is bound to be heard from in the near future. Regarding the



Ross 3 Passenger Roadster.

change in the motor, it has been decided to use a 6-cylinder instead of an 8, as in the past. The reasons for this change is explained as follows: The 6-cylinder is the popular motor today. It is the sifting down of all the experiments of the past. The public has learned that six cylinders are required for the necessary control and flexibility, but that the advantages derived from more than six do not compensate for the disadvantages of increased fuel cost and maintenance.

The six is the balanced motor. The Ross has always been a car of achievement, such as the recent stunt of climbing Lookout Mountain, Colorado, locked in high speed. In this event the car carried seven passengers, weighing a total of 1103 pounds, and this climb was made at an average speed of 27 miles per hour, without a single kick or complaint of the motor.

In Milwaukee recently a stock Ross car climbed the famous 19th Street Hill, a 19 per cent. grade an eighth of a mile long, from a standing start at the bottom, being thrown immediately into high and making the grade with apparent ease.

In Cincinnati a Ross stock car recently climbed the famous Fort Ancient Hill in one minute and ten seconds, locked in high. To the knowledge of the

Ross 7 Passenger Touring Car.

automobile men who witnessed the feat, no other car ever climbed that hill on high, which is so steep that farmers carefully lead their horses down the hill and never attempt to drive down.

Many other like achievements have demonstrated the Ross merits. These characteristics are due to the way the car is hooked up with the motor. In other words, it is a "balanced car." In changing to the six it has been proven that all of these characteristics will be retained, with the added advantage of fuel economy. In selecting the Continental Red Seal 3½x5¼, 6-cylinder motor, the firm believe they have the best motor obtainable for stability and latent power. Other slight changes will be made in the car to add refinement and convenience, but the motor is the only radical change made.

High ideals in manufacture and in service must be imparted to dealers and distributors, or the public will not realize on them to the fullest extent. To accomplish this all Ross dealers must be men of unquestionable standing and business ability, and a campaign for dealers is planned on this basis. The specifications are as follows:

Bodies — Seven-passenger, four-passenger suburban type, three-passenger roadster, coupe, sedan and town car. Design—Full streamline, one-man top. Unusually refined in design and finish. Upholstering—Rich, blue mottled Spanish leather. Windshield—Rain-vision; ventilating. Motor—Continental six-cylinder. Transmission—Selective sliding gears; three speeds forward and reverse; chrome nickel-steel gears and shafts. Clutch—Multiple disc. Axles—Full-floating rear; front I beam section. Starting and Lighting—Two-unit system. Lubrication—Force feed, pump driven to cylinders. Radiator—Cellular type. Ample capacity. Control—Center. Steering—Irreversible, left hand drive. Steering Wheel—Eighteen inches, corrugated, tilting type. Drive—Shaft drive; universal joints.

Digitized by Google

Springs—Semi-elliptic front (42x2 inches); semi-elliptic rear (57⅝x2½ inches). Wheel Base—130 inches. Wheels—Extra selected second-growth hickory. (Wire wheels furnished at additional charge). Tires—35x4½ inch non-skid, rear; plain front. Rims—Quick demountable. Horn—Motor driven. Instruments on Cowl—Speedometer, ammeter, ignition switches, oil pressure gauge, cigar lighter, electric lights, with 10-foot extension cord always ready with automatic take-up. Equipment—Tire repair kit, jack, pump, tire carrier, 1 extra rim, tools, etc. Weight—(7-passenger) 3250 pounds.

AUTOMOBILE LUBRICATION.

Where Dixon's Motor Graphite May Be Used With Good Results.

The proper lubrication of a car is of vital importance. One or two kinds of grease will not answer for all the parts because the conditions are different in each part and must be treated accordingly. If the following instructions are observed they will insure the best lubrication and a long-lived car.

Engine—Use oil recommended by manufacturer of your car. If there is a splash oiling system or combination of force feed and splash, add an even teaspoonful of Dixon's Motor Graphite to each quart of oil contained in the crank case. Add another teaspoonful of Motor Graphite after each 1000 miles of running.

Mix no graphite with the oil in a force-feed oiling system, but occasionally let a little graphite be inhaled through the air intake of the carburetor.

Do not use graphite in the crank case or transmission of Ford cars. It may be introduced directly to the cylinders through the air intake of the carburetor, or by special lubricators.

Transmission—Use Dixon's Graphite Grease No. 677 in all transmissions that require grease or heavy gear oil. Use Dixon's Gear Oil No. 675 in all transmissions that are intended for light oil lubrication. Clean out thoroughly once a year and refill to under side of main shaft.

Differential—Use Dixon's Graphite Grease No. 677 in all differentials, except as noted below.

Use Dixon's Gear Oil No. 675 in two-speed rear axles, in worm-driven axles and in the differentials of chain driven cars requiring light oil lubrication.

Use Dixon's Non-Leak Grease No. 680 for noisy gears and leaky housings. Remove all old lubricant before putting in No. 680.

Clean out the housing thoroughly once a year and refill to shaft level.

Internal Drives—Use Dixon's Graphite Non-Leak Grease No. 680. Apply sparingly.

Timing Gear Case—If there is no connection with crank case, use Dixon's Graphite Grease No. 677. Ordinarily the gears are automatically lubricated by the engine oiling system and require no attention.

Universal Joints—Use Dixon's Graphite Grease No. 676. Will not throw out. Examine every 1000 miles. Cup Grease No. 5 may be used if No. 676 is not obtainable.

Pump Cups—Use Dixon's Graphite Grease No. 676. Will not melt and run into radiator.

Overhead Valve Grease Cups—Use Dixon's Graphite Grease No. 676. Is not affected by heat.

Clutch Release Collars—When grease lubrication is required, use Dixon's Graphite Grease No. 676. It is not affected by heat.

Grease Cups—Use Dixon's Graphite Cup Grease No. 3, except in warm climates, where Cup Grease No. 5 is better. All cups should be given a complete turn before starting on a day's run.

Wheel Spindles—Use Dixon's Cup Grease No. 3 or Graphitoleo. Examine every 2500 miles.

Steering Gear Housing—Use Dixon's Graphite Cup Grease No. 3 or Graphitoleo. Examine every six months. Clean out and refill every year.

Driving Chains—Clean the chain and immerse it about twenty minutes in melted Graphite Motor Chain Compound. The chain will then be properly lubricated and will not pick up grit.

Springs—Loosen spring clips, jack up chassis and work a mixture of Dixon's Motor Graphite and kerosene between the leaves. This will prevent rust and assure easy spring action.

Tires—Use Dixon's Motor Graphite in place of talc. Will not allow tube to stick to casing, thereby preventing blow-outs.

Wheel Rims—A mixture of Motor Graphite and kerosene well rubbed into surfaces of rims will prevent rusting and sticking. Tire changes can be made quickly and easily. A thin coat of shellac and graphite also gives good results.

Multiple Disc Clutch—Add a teaspoonful of Motor Graphite to the oil each time the clutch housing is cleaned, which should be at least once in six months.

Leather Faced Clutch—Nothing is better than Dixon's Traction Belt Dressing for keeping the leather soft and pliable and thus preventing slipping. Neatsfoot oil or castor oil is also good.

Spark Plugs, Gaskets, Threaded Joints, Etc.—Use Graphite Joint Compound. It makes tight joints that open easily, and prevents rusting.

Electrical Equipment—Use no graphite in lubricating magnetos, generators or starting motors.

Motor Boats—Use No. 677 in the reverse gears, No. 676 or Cup Grease No. 5 in all grease cups and Motor Graphite in the cylinders. An application of Yacht Plumbago to the hull will reduce "skin friction" and increase the speed of the boat.

Motorcycles—Pack the change-speed gears and the wheel and brake hubs with No. 677. Graphitoleo is also an excellent lubrication for the hubs. Treat chains with Motor Chain Compound. It will increase the life of chains several times. Dixon's Motorcycle Belt Dressing will prevent flat driving belts slipping.

THOSE CHASSIS KNOCKS.

How the Car Protests at Its Treatment and How It Should Be Heeded.

From H. C. Brokaw, West Side Y. M. C. A. Automobile School, New York.—Does your car chatter? Does it talk to you and protest against running over holes and bumps in the road? If it does, it is a sign that you should pay attention to, a hint that you should do away with the knocks and clicks and chattering which annoy you and everybody else within hearing as you run along. That is, if you find them, for there are some noises so obscure as to defy detection even by the expert.

Such was the car which developed a sharp click when it was started forward or backward. It ran

Digitized by Google

quite a long time before it was possible to discover just what and where it was. It was somewhere in the back end, but so hidden as to defy detection. The rear axle was of the floating type, the construction in which the driving shaft is connected to the hub of the wheel by a number of flutings on the shaft, into which corresponding projections of the flange fitted. These had become worn and allowed sufficient play to cause a noise.

By walking alongside of the rear wheel while the car was being started and stopped, it was decided that the sound came from the hub of the wheel. The hub cap was removed and by placing the finger on the hub flange and end of shaft at the same time the play was detected by the sense of feeling, though it was hardly visible to the eye. The trouble was overcome by having the shaft welded to the flange. A few days later the owner happened to be at the agency and told what he had found.

"So glad you came," was the response, "for we have been looking for the same kind of a click a long time ourselves and the service station mechanics have not been able to locate it. They thought it was in the brake, but upon examination could see no reason for a click."

I have seen cases where the wheel was keyed on, and where the keys had acquired sufficient play to cause a continuous knocking, especially when the machine was being driven at low speed. This sort of knocking is more likely to occur with the four cylinder, slow speed engine than with the high speed, many cylindered type.

A mysterious knock sometimes may be traced to the torque rod, which is loose at the forward end, or to worn torque tube bearings, and in some cases the bolts fastening the torque rods to the rear axle become loosened, or worn, causing a knock, especially when going over bumps or dropping into holes.

The brake rods become worn and set up a continuous clattering on rough roads and this noise is accentuated if the tires are kept inflated at too high a pressure. As a matter of fact the car owner has the choice between the greatest life for his tires with accompanying rattles and discomforts, and riding at a sufficiently low pressure to subdue these noises and make life in a car worth living; of course there will be an attendant higher wear of tires.

Worn spring shackle bolts will not ordinarily cause knocking or rattling, but when going over bumps or holes the rebound of the body is sufficient to make the looseness audible. It can be overcome by having a new bolt put in, and prevented by keeping the bolts well lubricated.

Worn steering knuckle pins and tie rod bolts will be found responsible sometimes for knocks and rattles in the front end of the car. The remedy is obvious and the location of the noise is not hard to find.

In addition to these we have rattles due to tools being thrown loosely into the tool box, and sometimes the body bolts become loosened. The lamps occasionally jolt loose and the license plate bracket is sometimes so loose that it is audible as well as visible.

There are other knocks due to broken gear teeth and other broken parts and sometimes these broken teeth, loose nuts, bolts or pins, in gear or differential case, become wedged between the gear teeth and cause a knocking that is not hard to locate, albeit rather expensive to repair. And then there are the knocks and rattles from the hundred or more accessories which are attached to the chassis of many cars and which sooner or later develop defects and noise.

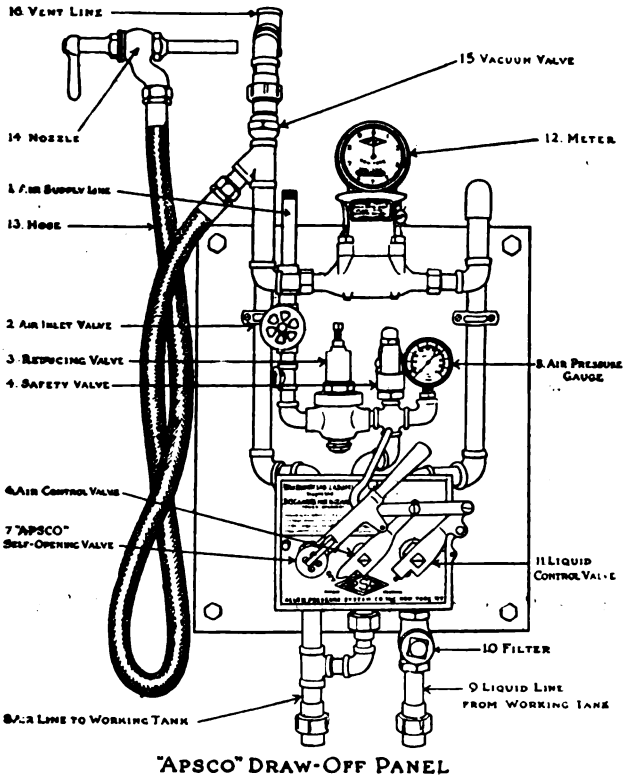
The up-to-date, well-designed car in perfect shape is practically noiseless and if a knock or rattle develops it indicates that something is worn or out of adjustment and needs attention. The owner who takes care to have all parts properly lubricated and kept tight need fear none of these annoyances, and proper attention means lack of annoyance when out touring; while slovenly habits will advertise themselves to everyone along the road.

The New Metz Truck.

Following more than a year of experimenting by Charles H. Metz and his engineers at the Metz plant, Waltham, Mass., the company announces that it is about to embark on the manufacture of a truck unit for converting new cars or used cars into high-duty one-ton trucks. Production is to start immediately. Different models of this truck unit will be made to meet the needs of varying transportation conditions. In connection with this announcement comes one of almost similar importance to the effect that the Metz is to turn out a tractor also. This will be a replica of the tractor that Charles H. Metz made for the committee of public safety to plow up unused land. It was designed on the spur of the moment and built in 48 hours, but has proven so successful in its nearly four months of daily service that many dealers near the factory have asked the company to market them. It will be known as the Metz Convertractor and can be attached to the front end of any make.

A car that is sure to make an appeal with the public is a taxicab with no taximeter in it.

NEW AND INTERESTING THINGS IN MOTORDOM



Apco Specialties For Ford Cars.

Discriminating owners of Ford cars the world over have learned to appreciate the merit of Apco specialties which are manufactured by the Apco Manufacturing Company of Providence, R. I. In this issue, a very interesting announcement appears from this company, in which the location and character of their accessories for the Ford are indicated on various cuts of the latest model Ford car. There are several diagrams devoted to this purpose, which will be studied with great interest by our readers. Dealers should especially be interested in the Apco line. Arrangements have been made to furnish Apco specialties in full assortment to dealers, packed in neat cartons, so that the packages make a very businesslike appearance, and it is true that nearly every live dealer who can make arrangements to handle the Apco line is bound to do so. Apco goods are now sold, by jobbers only, in 128 cities in the United States, but those who are looking for complete information in regard to this line should write at once to the Apco Manufacturing Co., Providence, R. I.

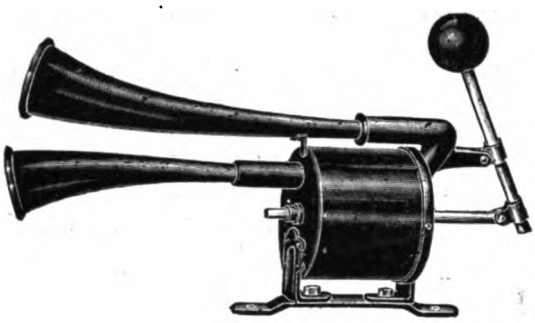
New Gasoline and Oil Storage Plant.

A new distributing system for transferring either oil or gasoline by means of air presure directly from a storage tank to an automobile or other receptacle, is now on the market and judging from the detailed description it is likely to soon come into general use in garages and repair shops. The system is undoubtedly flexible and safe, and does a wide range of work. It has been approved by the National Board of Fire Underwriters and carries an absolute guaranty against defect either in material or workmanship. Briefly stated, this pressure system device consists of two working tanks, one set above the other, the lower one of which is connected with the air pressure tanks commonly used in a garage for inflating tires. Only about 20 pounds of air pressure is really necessary although any pressure can be used. The principle is that the air pressure is always on the gasoline and you simply open a valve and this air pressure forces the gasoline out of the working tank into the tank on the automobile. The working tank is usually 60 gallons, but it can be any size. In operation the gasoline flows freely and rapidly and will fill the automobile tank very quickly and the gauge showing the amount of gasoline supplied to the automobile works continuously and of course stops whenever you close the valve. The advantages are rapidity of operation and its not being necessary to use a pump. The Allen Pressure System is low in price, considering its labor serving merits. Full particulars can be learned by addressing the Allen Pressure System Co., 16 West 61st St., New York.

"APSCO" DRAW-OFF PANEL

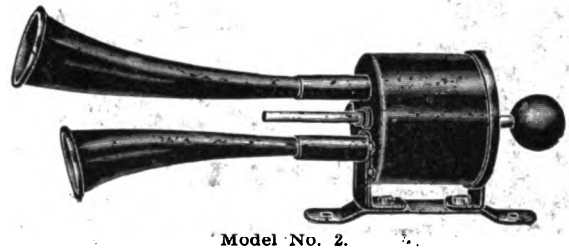
Lewis H. Scurlock Organizes New Company.

Lewis H. Scurlock has retired from active participation in the affairs of the M. & S. Corporation, still retaining his interests and remaining vice-president of the corporation. He has organized the Krom-niK Gear Company, with general office at 1100 Karpen Bldg., Chicago, Ill., and taken over the exclusive distribution of the M. & S. Differential, which will be manufactured by the M. & S. Corporation of Detroit; as well as the exclusive distribution of Anderson Rolled Gears made by the Anderson Patent Machine Process at Cleveland, Ohio. The Krom-niK Gear Company will act as the sales organization for both of these concerns. The Krom-niK Gear Company will specialize at first on differentials and drive gears for some of the smaller and more numerous cars, including the Ford, Chevrolet and Maxwell, as well as a general line of differentials and gears for the larger makes of cars.



Handy Repair Tags.

Stevens & Co., 375 Broadway, New York, have recently put on the market a line of auto repair tags which are extremely handy for the use of the busy repair man or dealer. These tags are so arranged that there is a complete record of the work, and mistakes and kicks in repair bills may be largely prevented by the use of these tags. They are made of large size, tough stock; one side printed for instructions and the other for a record of time and material. These tags are also numbered serially, with detachable card and space for dealer's imprint. They are sold at $5.00 per thousand, and no doubt many of our readers will wish to order these tags, as they are a great economy and convenience in any shop.



Warnola, a New Warning Signal.

It is a well known fact that in a warning signal for automobiles, it is necessary to have some sort of noise which can be readily distinguished above the roar of city traffic and that will carry for a long distance, but the manufacturers of Warnola contend that it is not necessary to have this noise of an offensive or disagreeable nature. The Warnola has a note which is insistent in its quality, yet entirely inoffensive, and will not fluster or confuse the man, woman or child who may have stepped into the path of the car. There are no diaphragms or springs employed in producing sound in the Warnola. Reeds are used, operated by a rush of air from a piston working in a double end cylinder. The piston is fitted with a felt ring held in close contact with the cylinder walls by a flexible steel band. By virtue of a special process, the felt is air-tight and indestructible. Short sharp blasts may be given by a quick movement or a long, distance-covering signal produced by a slower plunge of the piston. The illustrations herewith show two types of Warnola. Model No. 1 sells for $7.50, while Model No. 2, which is designed for small cars, sells for only $5.00. The tone is the same in the smaller horn, except that this horn is slightly different in construction and method of operation. The Warnola is likely to enjoy a large sale, as it is correct in construction, made of the best materials, with skillful workmanship and careful assembly. Readers who are interested should write for further particulars to the Warnola Manufacturing Co., 73 Wooster St., New York City.

Model No. 1.

Model No. 2.

JOHNSON'S CARBON REMOVER

Cures 80% of Engine Trouble

A dose of Johnson's Carbon Remover—The Engine Laxative—will make your motor run like it did the first 500 miles—quietly and full of "pep"—And your gasoline consumption will drop from 12% to 25%. You will save from $3.00 to $5.00 over any other method.

You Can Take the Hills on High Without a Knock

if you will keep your motor free from carbon with

JOHNSON'S CARBON REMOVER

That knocking in your engine—difficulty you have climbing hills—poor pick-up—pre-ignition and lack of power will all be overcome.

You Can Do It Yourself

For 25c—five minutes' time—and with no labor, you, yourself, can remove all carbon deposits. Pour an ounce of Johnson's Guaranteed Carbon Remover into each cylinder—allow it to remain two to twelve hours, then drive your car 10 or 15 miles. Results will surprise you.

Use It Every 1,000 Miles

If you will use Johnson's Carbon Remover at regular intervals, giving carbon no chance to accumulate, you will eliminate most valve trouble and your engine will always be at its highest efficiency.

If your dealer cannot supply you with Johnson's Carbon Remover, use attached coupon.

Write for our folder "Keeping Your Car Young"—it's free.

$1.00 Special Offer $1.00

S. C. JOHNSON & SON, Dept. AD8, Racine, Wis.

I enclose $1.00 for which please send me by prepaid express enough Johnson's Guaranteed Carbon Remover to thoroughly clean an ordinary four-cylinder motor four times.

JOHNSON'S PREPARED WAX

Now Made in Liquid Form

We are now making Johnson's Prepared Wax in ***Liquid Form*** as well as Paste—so that it may be more easily polished. Johnson's Prepared Wax ***Liquid*** is exactly the same as our Paste Wax except that it is a liquid. Apply with cloth, brush or spray.

Is Your Car Dirty, Grimy and Unsightly?

DO you know that you, yourself, can make it look almost like new and save the cost of revarnishing? All you need is Johnson's Cleaner and Johnson's Prepared Wax ***Liquid.***

JOHNSON'S CLEANER

entirely removes all stains, scum, road-oil, tar and grease from body, hood and fenders. It doesn't injure or scratch the finest varnish—simply cleans and prepares it for the Wax polish.

Absolutely Dust-Proof

Johnson's Prepared Wax Liquid gives a hard, dry, glasslike polish which does not collect or hold the dust. It preserves the varnish and protects it from the weather, adding years to its life and beauty. It covers up mars and scratches—prevents checking and cracking—sheds water and makes a "wash" last twice as long.

Johnson's Prepared Wax Liquid is very easy to use—it polishes instantly with but very little rubbing. You can go over a good sized car in half-an-hour.

Quarts.....$1.40 Pints.....$ .75
East of the Rockies

If your dealer cannot furnish you with Johnson's Automobile Products, we will pay the expressage to any point in the United States east of the Rockies.

The Sioux Valve Grinder.

The Sioux valve grinder is built to be a life-long tool, and cannot wear out by ordinary use. By continuous movement of the handle in one direction, the valve is given a reciprocating motion, always traveling slightly forward in one direction then in the opposite, thereby producing the motion that is absolutely necessary for perfect valve grinding. The end thrust ball bearing makes the

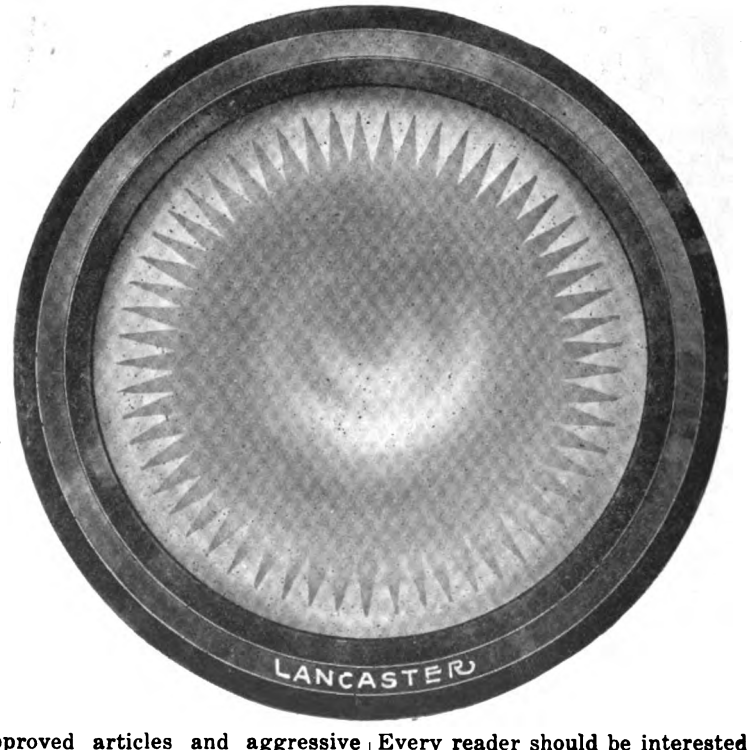
A New Valve Grinder.

grinder run easily and smooth. The gears are made of pressed steel. The grinder is provided with spring take-ups; that is, the springs act as the bearings and grinder wear, putting the gears in deeper mesh and the bearings in a more rigid position. The Sioux valve grinder has a high grade finish and nickel plated, and is provided with five driving points and one long extension shank. This tool is made by Albertson & Co., Sioux City, Iowa.

The Saybrook Carbon Brush.

This is a new brush which has recently been placed on the market by the Chapman Brothers Company, Saybrook Point, Conn. The brush is novel in construction and it has many good qualities. It is really two tools in one. By the method of construction used there is a ring of bristles with outside length below the bottom of ferrule of five-sixteenths of an inch. This makes a short and very stiff bristle capable of cutting the hardest carbon deposit. Inside this ring of bristles there is a length of eleven-sixteenths of an inch below bottom of the plug. This length allows of a very considerable flexibility and permits reaching into all irregularities in the cylinder head casting and also insures covering thoroughly the rough unmachined surface. The bristles are mounted around the retaining plug, after which this plug is forced into place under a two-ton pressure. This ferrule is then crimped midway of the length of the plug, making an absolutely positive mounting. The bristles are permanently anchored and cannot work loose. The handle is mounted in the same manner. This brush will appeal to repair men, garage owners and car owners who look after their own cars. The brush is simple in construction and moderate in price, yet it exactly fulfills the purpose for which it is made. Readers who are interested should write for descriptive circulars and prices direct to the manufacturers at Saybrook Point, Conn.

Grinds Four Valves at Once.



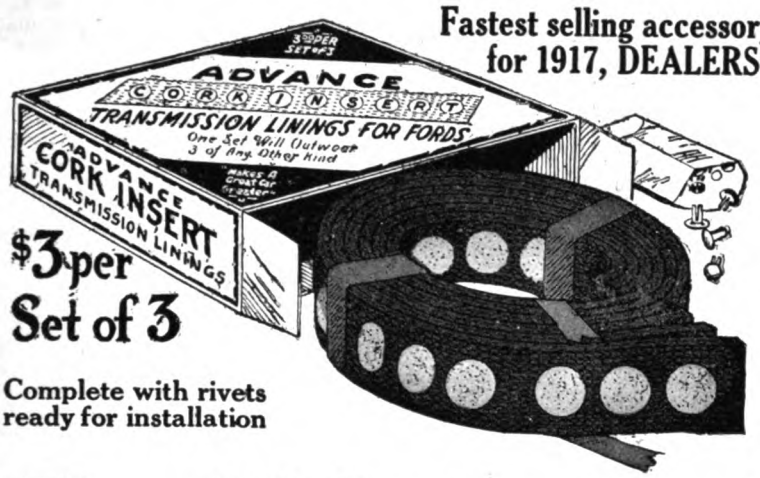
A new valve grinder which grinds four valves of the Ford motor at one time, thus saving 50 per cent. is the latest thing on the market. It works so accurate that a boy can do a perfect job with it and it ought to be in every repair shop in the country. The price is low; so low that any car owner can well afford to own one. Write for particulars, Universal Pure Air Pump Co., 1607-11 Prairie Ave., Chicago.

A New Company in the Automobile World.

A company whose officers and directors are closely affiliated with some of the largest financial interests of Pittsburgh, has entered the automobile field. The activities and developments of this organization will, undoubtedly, be of interest to the entire automobile industry. The Iron City Products Company has a broad Pennyslvania charter which grants to it the right to manufacture any article from iron or steel, but it is understood that the initial development will have to do largely with the manufacture and marketing of such parts as have previously met with the most rigid tests; and are identified with the aircraft, marine and automotive industries. The company is now testing out a number of inventions bearing upon the increased efficiency of automotion and will take up and exploit such of these as meet with their requirements and satisfy all trials in actual operations. The trademark "ICP" will be placed upon such approved articles and aggressive sales and advertising campaign will follow. The company has for several months been marketing an improved piston ring which will be produced in large quantities in their new factory. This "ICP" ring for pistons is said to incorporate a new engineering principle and has met with a remarkable showing in various tests and received the endorsement of well-known engineers. The personnel of the officers and directors of the Iron City Products Company is an assurance that it will play a large part in the development and merchandising of new and meritorious articles in these industries. It is understood from officers of the company that while they now have a number of articles of proven merit, they are continually in the market for new and practicable products in their field. Plans have been made to introduce the piston ring to the trade and public early in the fall.

The Star Lens.

Nearly every state in the country now has a law against glaring headlights, and the minds of the best inventors of the country have been busy with the important problem of how to fulfill the requirements of the law, and at the same time furnish the driver of a car with a satisfactory headlight. The Star Lancaster Diffusing Lens is the result of a careful scientific investigation and study, and it is believed that everything most desirable in a headlight lens has been accomplished in the creation of this device. With this lens all the brazen glare is toned down, so as to actually give more illumination, distributed where it is most needed. With a stream of silvery rays, a diffused light, the fog, mist or darkness can be penetrated much further than with a clear glaring light. The light is thrown sideways as well as forward, and a driver can go to the extreme edge of the road without being ditched. Corners can also be turned sharply and quickly with perfect safety. These lenses fit every car. They work equally well with gas or electric light, easily installed.



Every reader should be interested in this new lens and should write for full particulars direct to the manufacturers, the Lancaster Lens Company of Lancaster, Ohio.

CORK INSERT

Transmission Linings for Fords

Fastest selling accessory for 1917, DEALERS!

$3 per Set of 3

Complete with rivets ready for installation

They Make the Ford Brake BRAKE

YOU know how the Ford jumps when it starts, and jerks when it stops—how it shivers and jars every time the brake goes on. Here is something that puts velvety smoothness in the Ford Transmission, so that it goes into low or reverse like a high-priced car. It starts gliding to a quiet stop at the first touch of the toe on the brake. No more chatter, no more jar—regular big car stuff.

Ordinary transmission fabric becomes glassy surfaced and hard and does not grip unless excessive pressure is brought to bear. Then it suddenly grabs and slips—causing jars and the mechanism-killing vibration. The corks in Cork Insert Linings eliminate the slipping, the jarring, the vibration, of starting and stoping. In addition Cork Inserts outlast two to three sets of ordinary linings.

Get Cork Inserts, Now, Dealers!

Cork Inserts (both Transmission Linings and Fan Belts for Fords) are being advertised to your trade in the Saturday Evening Post and leading trade papers. They are selling by the thousands. Your customers know about them and are ready to buy as soon as you are prepared to sell them. They give better service with increased economy. Use the coupon and send your order today for Cork Inserts. Your jobber will get full credit.

Car Owners! *Send the coupon for Cork Inserts. Your dealer will get full credit.*

And Now This New Big Winner

ADVANCE CORK INSERT FAN BELT FOR FORDS

Most motor troubles are caused by overheating. Overheating would largely be avoided if the fan were kept fanning by a belt that didn't slip. The slipping of the ordinary Ford Fan Belt runs between 25% and 50%. It's bound to get slippery from the soaking in oil and water and the polishing action of service. Cork Insert Fan Belts

Keep the Motor Cool —They Don't Slip

Corks are inserted into high grade, waterproof oak leather, and backed by heavy waterproof fabric. The corks stop the slipping. They are unaffected by water or oil, grease or dirt. They *retain* their gripping qualities throughout a service several times as long as ordinary belts.

$1 for 1917 Ford

—85c for earlier models

Keeps the fan fanning —keeps the motor cool

There Will Be 1000 New Smith Form-a-Truck Dealers Appointed in the Next 90 Days

To each we give a money-making proposition that CANNOT be EQUALLED in the industry

Startling as has been the success of Smith Form-a-Truck dealers in the past, it does not compare with what we have in store for the coming season.

A year ago we said Smith Form-a-Truck was the best proposition of the year — ***and we proved it.***

We say NOW the proposition for the coming season will be infinitely greater.

Smith Motor Truck Corporation

Manufacturers of Smith Form-a-Trucks

Executive Offices and Salesrooms, Smith Form-a-Truck Building

Michigan Avenue at 16th Street, Chicago

Kansas City Branch, 1808 Grand Ave. Southern Branch, 120 Mariette St., Atlanta, Ga.

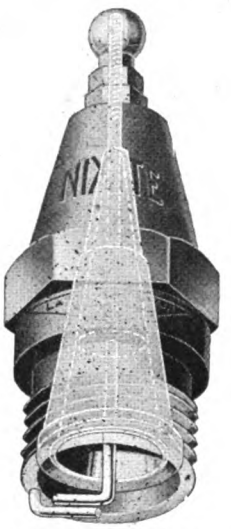
"Buy Your Trucks Early."

Do your motor truck buying early. This is the slogan which is now being heralded across the country for the reason that the government is looking about, with the idea of ordering some 70,000 trucks. Which means that the farmer, the factory owner and the merchant of progressive tendencies ought to get his order in now, to assure him of his vehicle. For when the U. S. A. wants things, it usually manages to get them. Users of light trucks need not worry, however, with the "attachment" company on the job. Utilization of the pleasure car chassis permits the quick change from a touring car to a ton truck, as is the case with the Smith Form-a-Truck. This firm is not handicapped so long as the pleasure car makers continue to produce their machines, for an output of 40,000 this year is predicted by the production manager of the Smith Motor Truck Corporation, of Chicago.

An Auto Light Reflector.

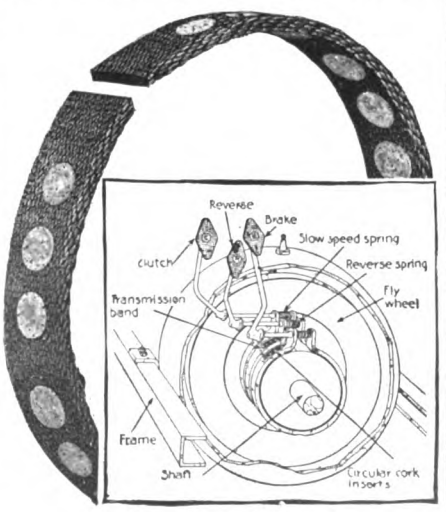


The Amco is a new auto light reflector which has been licensed by five states and has received unqualified endorsement by all who have seen it. The illustration will give a fair idea of what this device is and how it works. The price is only $1 per pair. It is easily installed and causes the rays of light to be sent in whatever direction it may be necessary. It is manufactured by the Art Metal Mfg. Co., Cleveland, Ohio.

The La French Spark Plug.

The rapid growth of the La French Spark Plug Company of Dayton, Ohio, has compelled them to seek better facilities and larger quarters. This prompted the organizing of a company with a capitalization of $100,000 with its new location at Columbus. The low grade fuel has played an important part in the designing of motors and ignition along with carburetion. The engineers are keen and alert in taking advantage of scientific research work to bring out a blue hot fat spark in the form of ignition to burn up and consume the low grade gasoline after it leaves the carburetor. This company is placing on the market a most remarkable power spark plug designed on the principle of a dynamo, so arranged to take the current with the least possible resistance, thus stealing the life or current away form ordinary spark plugs. For this reason they are sold in full sets at $1 each.

The greatest troubles of today that the motorist has to contend with, are broken porcelains and lost compression, and the La French Power Spark Plug

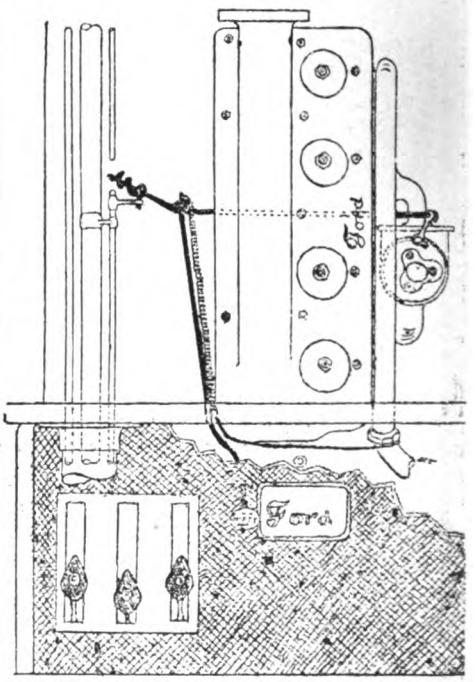


Note the Insulator.

Company has overcome both these difficulties with the use of their new Nix-ite insulator, which is inserted inside an independent steel shell.

Cork Insert Linings.

Cord insert linings were originated to make the planetary transmission easier of operation and more efficient through the elimination of slipping. In addition to doing this, it has been found that they give a wear from two to ten times longer than transmission linings of the ordinary plane surface type. The lengthened service of cork insert linings is due both to the gripping qualities and the wearing qualities of cork. Into the highest grade transmission fabric, buttons of cork are inserted at regular intervals. The corks are a bit thicker than the fabric itself, and make the first contact with the transmission drums. Because

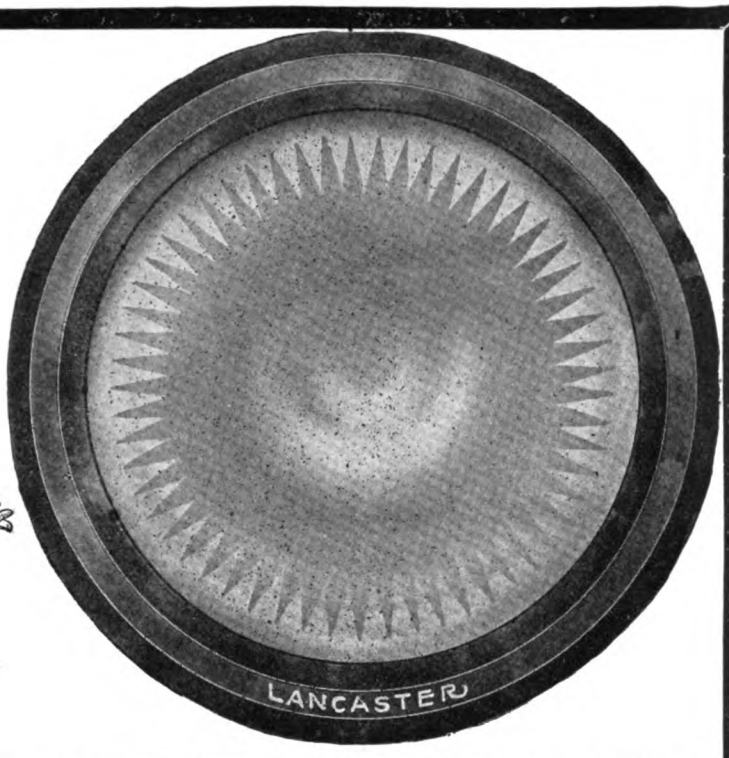


How They Work.

of the high coefficient of friction of cork and steel, the response to the pressure of the brake or speed pedal is immediate, and a smooth, velvety stop or start is made. The corks prolong the life of transmission lining because they eliminate the wear and tear of excessive pressure, of burning friction, aggravated by slipping, and because of the wearing qualities of cork itself. Cork is not affected by soaking in oil, does not harden from pressure. It wears very slowly, retains its place in the fabric, and holds is gripping qualities as long as the lining is in use. Cork insert linings are manufactured by the Advance Automobile Accessories Corporation of 56 East Randolph St., Chicago, and retail at $3 per set of three.

Accelerator for Ford Cars.

The nifty foot accelerator for Ford cars gives a quicker and more even pick up than is possible with the hand throttle; also enables you to maintain a much more even speed on the road. It leaves both hands free to handle the steering wheel which is desirable at times as when driving on muddy or sandy roads and on crowded streets. When driving in cold weather with this foot accelerator on, the hand throttles may be bent down slightly, thus enabling you to use a large pair of mittens without interfering with the throttles. It weighs less than 8 ounces complete. It can be attached in five minutes' time. It does not interfere in any way with the use of the hand throttle; either one takes effect immediately when it is touched, regardless of where the other is set. Guaranteed to give satisfaction. Price, $1.35. Manufactured by Will A. Sapp, Elgin, Nebraska.



Nifty Accelerator.

Parry Mfg. Co. Donates Ambulance Bodies.

Six motor field ambulance bodies constructed by the Parry Mfg. Co. were presented recently to the Indiana National Guard for use of one of its newly motorized field ambulance companies. The offer to make and donate these ambulance bodies was made to the Governor of Indiana some time ago and it was promptly accepted with thanks from the chief executive.

OUR LONG EXPERIENCE

THE BETTER QUALIFIES US TO MAKE THE BEST LENS—YES,
THE VERY BEST—

THE STAR LENS

All Danger is Avoided—*The Law is Obeyed*—Night Driving is Made Safe and Pleasant

Automobile Lighting is "our middle name"—we've been at it for years—now, honest, just between ourselves, if you had your mind made up to buy Lenses, either as a jobber, dealer, or car owner, isn't it a ten to one shot that the order would go to the house with the most experience at its back? Yes! Sure! Just naturally the order would drift that way —Why? Well, because buying Lenses cannot be likened unto the buying of soup greens. We all know that diffusing Lenses have been going through the experimental stage—that's why our customers flocked to us, as soon as we announced our finished product—they knew we'd have the goods.

The Star Lancaster Diffusing Lens

is the highest point ever reached in Auto Headlight Lens making. All our experience is there—and experience is good if not bought too dear. All the brazen glare is toned down so as to actually give more illumination, distributed where most needed. This is scientifically accomplished. The stream of silvery rays—the diffused light—penetrates fog much further than a clear, glaring light.

All shadows and dark spots often mistaken for ruts are eliminated. The light is thrown sidewards as well as forward. A driver can go to the extreme edge of the road without being ditched. Corners can be turned sharper and quicker with perfect safety.

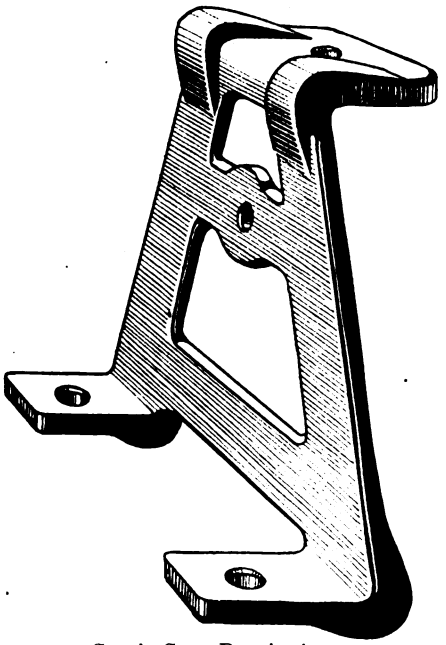
The Bailey Ball Thrust Bearing.

This is an exact replacement bearing to replace thrust washers at the left or gear side of the Ford car and Chevrolet 490 differentials. This device is claimed by the manufacturers to be an efficient remedy for axle difficulties, noisy or broken gears. This invention is the work of a master engineer and it will fit to the thousandth part of an inch, and will positively keep gears in proper mesh and make them run quietly and last indefinitely. Dealers, garage owners and repairmen throughout the United States and Canada are stocking this bearing, which retails at only $3.75. A liberal discount is offered to dealers, and readers who are interested should send their orders and inquiries to the Ahlberg Bearing Co., 2634 Michigan Avenue, Chicago, who are the sole distributors for the United States.



New Labor-Saving Devices.

The Hudson Motor Specialties Company, Real Estate Trust Bldg., Philadelphia, Pa., has put on the market a universal jointed valve-grinder which seems to be quite an improvement over

Valve Grinder and Parts.

the ordinary method of valve grinding. This tool is undoubtedly efficient in grinding the valves of the fourth cylinder of the Ford engine which seems to give more trouble than any of the other cylinders, and which it is difficult to reach for the purpose of grinding. It is of unusually low cost and does the work accurately and with little labor. The same firm makes a crank case repair arm which is illustrated herewith.

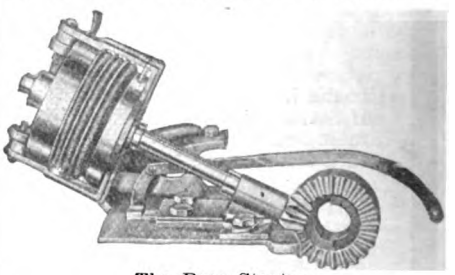
Crank Case Repair Arm.

With this device you can repair the engine in case the crank case breaks in a short time and at little cost.

Standard Roller Bearing.

An event of interest to New England automobile owners in general and to dealers and garage men in particular, is the opening of a Boston branch house of the service sales department of the Standard Roller Bearing Company of Philadelphia, which will be headquarters in New England territory for all their products. Attractive quarters have been secured at 163 Massachusetts Avenue in the center of Boston's "automobile accessory row" and this new store will be in charge of Joseph R. MacCollum, well known to the trade, having been for several years purchasing agent for the Packard Motor Car Company of Boston. This is the first of series of branch houses of the service sales department of the S. R. B. Company which will be opened in the near future in approximately fifteen or twenty of the leading cities of the United States. These branch houses will cater particularly to the interests of dealers, garage men and consumers covering all supplies and service pertaining to S. R. B. products.

The $295 Ford Truck.



Business men are awakening to the fact that it is folly to buy a new truck or do without, when a Ford can be so easily and quickly converted into a first class 2500 pound truck, at such a surprisingly low cost. There's a good, profitable harvest in this field for live dealers. The future needs for small trucks can hardly be estimated. When trucks can be procured at so low a cost, thousands of uses will be found for them, which are as yet unthought of. Your imagination can run riot along this line without exceeding the possibilities. The low upkeep of the Ford will result in fleets of Ford trucks replacing the heavier kind, etc. Be ready for the harvest. The Andaford attachment, composed of chassis, heavy artillery rear wheels, springs, chain drive, etc., made to attach rigidly to original Ford chassis by simply removing pleasure car body and rear wheels, is designed by men associated with the auto industry ever since it was an industry. In construction, utility and quality of materials it is supreme and the price—$295, will make it a ready seller. It is made by the Andaford Truck Co., Jefferson and McDougall Aves., Detroit, Mich.

The Stanley Steam Cars.

Word comes from the Stanley Motor Carriage Company of Newton, Mass., that from this time on Stanley cars will be supplied in only one chassis size. This is the standard 130-inch wheelbase model, such as they have made for the past three years with three, five, or seven passenger bodies. For many years the Stanley manufacturers have been furnishing a special over-size chassis and power plant for heavy duty commercial service, twelve to fifteen passenger mountain wagon service, and general bus service. The power, flexibility and economy of steam power adapts itself unusually to these extreme uses and this department of the business has flourished for years. The decision to discontinue these models was induced by a growing demand for Stanley cars which the factory is having difficulty in keeping pace with. The concentration of production on a single chassis size will help the output of the Newton works and assure better deliveries on the regular line. Whether it will be a permanent policy of the Stanley Motor Carriage Company to withdraw from the bus and mountain wagon fields, is not said, but their factory capacity is being increased and the move may be only temporary.

Bear Starter Spins the Motor.

An ingenious invention for starting Ford cars from the seat is the Bear starter the big feature of which is a three-to-one gear, driven by a tapered drum, and placed under the hood independent of all working parts. The drum revolves three times with each operation, spinning the motor a complete revolution over two compressions and past two

The Bear Starter.

ignition points giving both leverage and speed. Giving the handle a pull from the seat, the pull is transmitted by flexible cable direct to the drum which immediately begins to revolve at great speed and in an instant the second compression point has been reached, the motor has drawn in a full charge of gas and generated a good hot spark. There are no corners or pulleys to work around making the pull easy and wear on the cable negligible. The starter is bolted on to the motor base. No holes need to be drilled and no parts disturbed. Manufactured by Bear Mfg. Co., Rock Island, Ill.

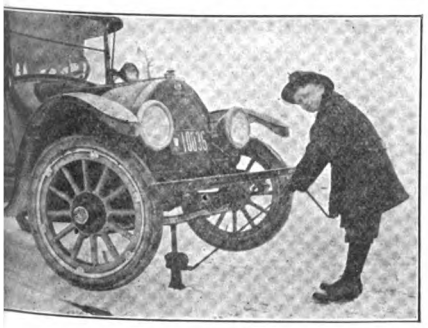
Food Supply is Decreasing.



The food supply for humans is decreasing, says T. J. Hudson, sales manager, motor truck department, Chicago Pneumatic Tool Company, Little Giant Building, 1615 Michigan Ave., Chicago, Ill. Its price is increasing. Yet horses are being daily fed it. 17,000,000 work horses each consume 136 bushels of oats per year, or 2,312,000,000 bushels of what might be oat products, the most nourishing food for human beings. Again, the U. S. Department of Agriculture says it takes over three average acres to supply a human being, and more than five for a horse. So every team of horses costs more to maintain than three human beings. The expert analysis continues, "Wherever a team of horses is employed to do work that can be done more effectively and more economically by a motor-driven vehicle, the up-keep of those horses is seriously menacing the food supply of human beings even if it is not robbing three human beings of food. The great war will be won or lost by food. All the authorities are agreed upon that. Even if there be no actual pinch of hunger, the rising cost of foodstuffs is bound to crystallize into an irresistible public opinion whose object will be to compel the conservation of food. Those who employ horses to do work that motor trucks can do better may have to justify the use of horses."

It is presumed that the large cities will require all tenement automobiles to be equipped with adequate fire-escapes.

An Extraordinary Jack.

The Rees jack, recently introduced by the Service Corporation of Pittsburgh, Pa., possesses many novel features. The fact that this jack can be operated while standing erect at a sufficient distance from the car to insure perfect freedom of action, will doubtless prove a boon to many motorists. Its long crankhandle enables the operator to swing it under the car, push it into the exact position desired, raise and lower the car, and

How It Operates.

remove the jack, all without stooping under the car or actually handling the jack itself. The Rees jack has only 4 working parts, and contains no springs, pawls or ratchets. It was developed in railroad yards, lifting freight cars and passenger coaches for the replacement of bearings. It is an extremely powerful and efficient lifting device, silent, steady and safe. The 2-ton jack, for motor car use, is tested with a 5-ton load, yet it is practically no larger or heavier than other jacks. The ease and swiftness with which this jack can be handled, together with its safety and cleanliness, seems to assure it a warm reception by the trade.

Harvard Pocket Battery Meters.

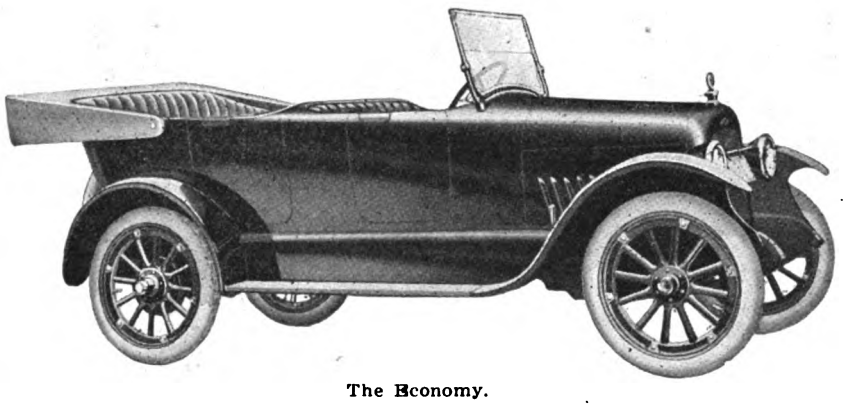
The Harvard Electric Co., 525 W. Van Buren St., Chicago, Ill., are manufacturers of the Harvard Pocket Battery Meters, which are high grade instruments of the permanent magnet type. They are light, handsomely nickel-plated, and of convenient pocket size. They are accurately calibrated and guaranteed for two years. Neither the temperature nor the weather affects their accuracy. They may be read in any position, with or without the use of the flexible cable.

They also make ammeters for testing dry cells. These instruments indicate the direction of current as well as its strength. A flexible cable accompanies each instrument so that the total effect of the whole battery may also be easily determined. A new circular illustrating the above material has just been issued and those interested are requested to write for a copy.

New Accessory Manufacturers.

The Bear Manufacturing Co. of Rock Island, has just been incorporated under Illinois law with a capital stock of $200,000 and promises to be a large manufacturer and handler of Ford accessories. The company has developed a number of excellent accessories most of them being particularly adapted to Fords. A. I. Sandbo is the inventor and some of his inventions are now known the country over and are in use around the globe. Among the accessories now ready for the market are the Bear mechanical starter for Ford cars, the Bear Primer, Bear gas generator, Bear running board support for Ford cars, Bear vulcanizer, Bear draft shield, Bear oil saver, Bear radius rod and Bear crank handle release. Each of these articles are fully covered by patents and facilities are at hand for their manufacture in large quantities. The Bear primer is another of the company's products. It is a gravity primer with a self-measuring chamber which gives just the right charge every time and carries it to both ends of the manifold, right at the intake ports. It is non-leakable and operated by simply lifting a double acting needle valve.

Tire Repair Equipment.



The Akron Rubber Mold & Machine Co., 917 Sweitzer Ave., Akron, Ohio, manufacturers of Tip-Top Ti-Re-Pair Equipment, after maintaining their price of $125 for their Type F Equipment, big capacity. self contained vulcanizer, for months in spite of the steadily increasing cost of raw materials, have been forced to advance the price of this equipment to $150. As a result of the price and specifications published, orders poured in from the trade in all parts of the country, taxing the factory to the utmost to keep up with them. Now with the present cost of raw materials, the manufacturers claim that their Type F Equipment, big capacity, self contained vulcanizer, with the specifications and high quality of this outfit, is better value for the money than is now offered elsewhere for anywhere near the price. Equipment consists of two cavities: 2½-3 and 4½-5, with reducing shell to take 3½-4, on which practically all sizes of inside work can be done. 2½-3, 3½-4 and 4½-5 bead molds in either quick detachable or straight side furnished with outfit.

The Economy Motor Car.

As will be seen by the illustration, the Economy Motor Co. of Tiffin, Ohio, have designed a most graceful and attractive automobile. It is an assembled car, and that is considered by some a decided advantage rather than otherwise. The principal specifications are given herewith and it will be seen that they are all of the highest class.

Four-cylinder cast en bloc, high speed type; bore 3¾ inches, stroke 4¼ inches, 36.9 horsepower, at 2800 revolutions per minute. Crankshaft and camshaft of nickel steel specially heat treated. Carburetor—Schebler. Model "R," air adjustment from dash. Ignition—Connecticut automatic in connection with coil and distributor, current taken from the storage battery. Lubrication—Splash system supplemented by plunger pump effected by the camshaft. Cooling—Thermosyphon in connection with a honeycomb radiator. Clutch—Disc type running in bath of oil. Transmission—Center control ball bearing, nickel steel gears, three speed forward and reverse. Electric system—Two unit Dyneto, chain driven generator with timer head, ammeter on dash. Starter with Bendix drive to the fly wheel. Storage battery—Willard, 6 volt, 80 ampere. Wheelbase 115. At present the Economy Motor Company is confining its efforts to only two models—the touring car and the Thre-Dor roadster. The touring car is large and roomy and will easily accommodate five passengers. The Thre-Dor roadster as implied by its name is built with only three doors, one on the left and two on the right, and will accommodate five passengers without crowding. Prices are as follows: Touring car or Club roadster, 4 cylinder, $1040—either type, 8-cylinder, $1395, f.o.b. Tiffin. For further information, write the Economy Motor Company at Tiffin, Ohio.

The Economy.

"Care Saves Wear."

This is the title of a most attractive little pocket size booklet of 32 pages, issued by the Federal Rubber Company of Cudahy, Wisconsin, for the benefit of tire users. And it is doubtful if any other three small words could be found, which, framed into a sentence would be of greater interest and benefit to automobilists in general. In this booklet practically every trouble to which a tire is subject has been illustrated from photographic reproductions of actual specimens gathered from many of their service stations, thus representing the results of service over practically every kind of road throughout the United States. In each instance the cause of the trouble is clearly explained, and suggestions offered for its prevention. Carefully studied and practiced, the valuable knowledge contained in this booklet will enable any motorist to largely decrease his repair bills and very materially increase his tire mileage.

Guarantee Visible Gasoline and Oil Pumps.

These pumps for garages, dealers and gas filling stations will surely command a ready sale as they have many distinct advantages. The visible measuring device is extremely handy. These pumps are guaranteed to be absolutely accurate as to measurement and by their use, all hand pumping is eliminated. There are no parts to adjust or get out of order, and these pumps are easily cleaned and positively filter gasoline. One or more grades of gasoline can be handled through one pump. These pumps are not affected by temperature. They hold no gasoline in the hose and they are absolutely self-measuring. Readers who are interested should write for printed matter and full particulars direct to the manufacturers, the Guarantee Liquid Measure Co. (Hepburn Walker, Distributor, Farmers Bank Bldg., Pittsburgh, Pa.)

Prismolite Lenses.

The Prismolite Company, Columbus, Ohio, are having wonderful success in marketing the improved type of Prismolite lenses which were first offered to the trade in May of this year. Prismolite lenses are made of plate glass. They are convex, and on the inner surface of each lens are over 20,000 prismatic surfaces, 256 to the square inch. Each of these prisms collects the blinding glare from the headlight and breaks it up—diffuses the rays, making a soft mellow light which illumines the roadway and 30 feet on either side. Just below the center of the lens is a clear glass bullseye which throws a beam of light 1,000 feet ahead. Thus light is furnished wherever it is needed—on the roadway in front of the car, on the sides of the road, everywhere except in the eyes of the approaching pedestrian or driver of another car. Prismolite gives, beyond doubt, the clearest, strongest, brightest, yet softest illumination of any lens now on the market. It may not be generally known that the Prismolite Company produce more automobile glass than all other manufacturers combined. The retail list price is $3.50 and $4.00 per pair, according to size.

New Dixon Booklet.

The Joseph Dixon Crucible Company have just published a new booklet descriptive of their graphite automobile lubricants. This booklet has for its introduction a story of the Roman Emperor who covered the world with leather and the connection between this story and their graphite lubricants is very cleverly drawn. A booklet will be sent to anyone who will write the Joseph Dixon Crucible Company, Jersey City, N. J., giving the name of their car and dealer.

Ford Car Accessory Exposition.

There will be held at the Coliseum in Chicago from September 22nd to 29th, a National Exposition for Ford car accessories. This unique show has received almost universal endorsement, not only of those interested in Ford car accessories but by other big concerns and it promises to be an occasion of a good deal of interest and importance. Automobile schools have been invited to participate in the Ford accessory show and the Coliseum Annex has been set aside exclusively for their educational demonstrations. There will be no exhibits in the balcony and basement of the Coliseum; these portions of the huge exposition building being used for promenade, lounging and smoking rooms and places of entertainment. The national colors and American flags will be the feature of the show decorations, the work being in charge of the leading festival decorator in the United States.

Carries Nearly All of the Ford Load.

The Ford power plant is built to carry the ordinary equipment and body of the Ford passenger car, plus five passengers, at most. Its surplus strength is sufficient to care for ordinary overload. It does the work for which it is built. But the Ford power plant will pull many times the weight it will carry—and on this basis the Phenix truck maker is built. There is no danger of overloading the power plant of the Phenix truck maker, or of putting undue strain on the motor. At no time is the motor or car—even when hauling the maximum load—subjected to greater strain than when traveling at moderate speed as a pleasure car. With its massive construction and broad, heavy, artillery type wheels, it carries 90 per cent. of the load, safely and easily. The Ford part of the unit merely pulls it. And, besides, ball bearings in the bell housings relieve Ford axles of strain and prevent breakage. Extra heavy springs carry the load with ease, and the efficient brakes operate metal against metal. The capacity is 1½ tons and the price is but $350. When you purchase a truck extension get only the best and strongest and thus avoid trouble.

There's a Great Call

for this popular pump

"Ninety Pounds Before You Know It"

It's so *easy* and so *sure*— requiring so little muscular effort that even a woman can easily pump up a tire to standard pressure. Power pumps may fail—foot pump disappoint you, but a

YANKEE
90 Pounds Before You Know It
PUMP

is always on the job. It's not an up-and-down, back-breaking, "push-and-pull" motion, but an easy swing of the arm, standing erect, with a pump so perfectly made and adjusted that it answers every thrust with full volume of air. Make a Yankee Pump part of your necessary equipment. Ask your dealer about them.

Training a five-inch gun aboard one of our Dreadnaught Battleships

DREADNAUGHT TIRES

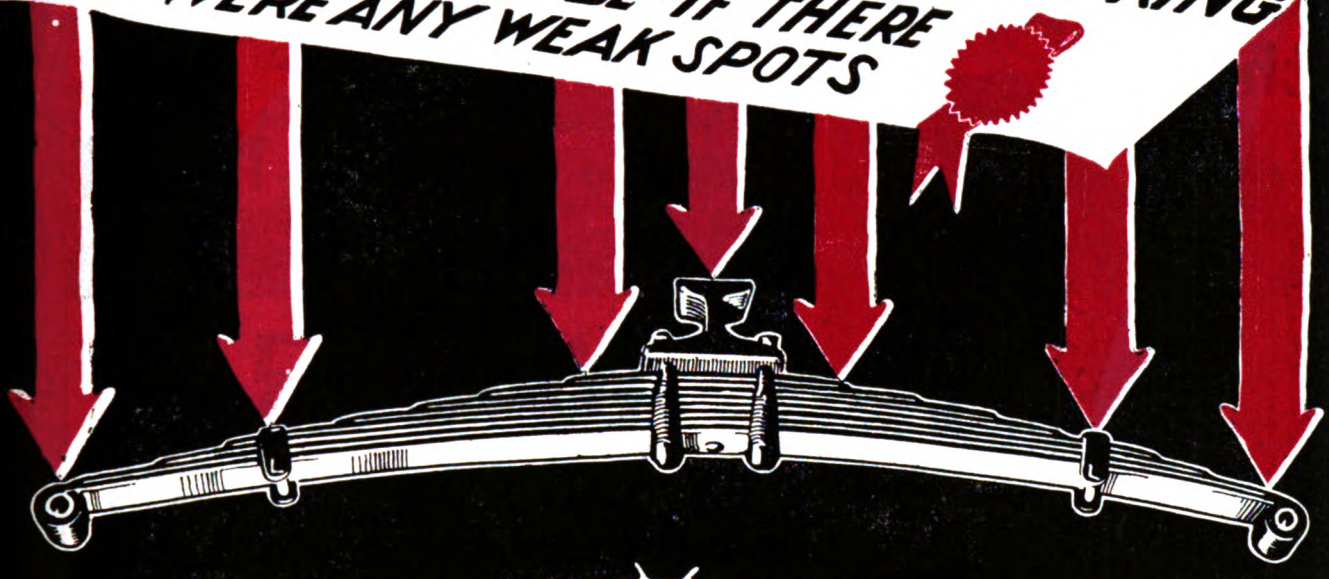
have set a new mark in the tire world because of their toughness, durability, resiliency, and smooth-riding qualities. They deliver mileage far in excess of their guarantee.

5000 MILES GUARANTEED

DREADNAUGHT Red "Silent" Vacuum Tread is a positive anti-skid—the bar through the centre of cups prevents clogging, avoids "drag," minimizes noise and road friction, and "holds" the road. DREADNAUGHT Red Ribbed Tread is easy to steer and successfully supplants the old time plain tread. The color scheme—the *red* rubber treads contrasted with the soft-toned ivory side-walls—adds smartness and distinction to the car.

Use SUPER-DREADNAUGHT RED INNER TUBES in Dreadnaught Tires—they are thicker and stronger than ordinary tubes. Dealers find them excellent leaders for their accessories stocks.

We have an exceptional proposition and assure excellent service and territorial protection with intensive co-operation from our organization. Write or wire, Department "Y"



Beautifully illustrated Booklet "The Evolution of the Battleship" by Henry McDonald Spencer, sent free on request.

Our Guarantee
THE SAME AT ANY POINT ON SPRING
IT WOULDN'T BE—IF THERE WERE ANY WEAK SPOTS

The manufacturer of a spring knows more about his product than any outsider does. His guarantee is going to be just as liberal as quality will allow. So it follows that the broadest guarantee covers greatest spring value. Providing, of course, the guarantee is given by a *responsible* maker.

Higgins Quality Springs
FOR REPLACEMENT

are guaranteed alike at *all* points. There isn't a weak clause to leave a loophole for weakness of construction. Our guarantee is strongest because years of the most rigid usage have proved Higgins Quality Springs equal in every *section* to all demands.

This Alone Should Show You Where To Obtain Greatest Value

We *know* Higgins Springs will stand up and render satisfactory service in the center where 90% of all spring breakage occurs, for under our scientific form of center building all weakness has been done away with. Instead of a bolt and a hole which rob the spring of just so much support—instead of a hump, which stiffens the center and causes equally great breakage outside malleable that holds leaves together—we employ the *nib* form of retaining leaves securely in place.

This improved design grips centers safely in position—it possesses strength which bears the brunt of heaviest loads and hardest bumps, and *allows* the "give" essential to real riding comfort. We employ only best grade of motor car spring steel of special analysis—tempered in furnaces and quenching baths constructed especially for us. Subjected to most exacting tests for defects in elacticity, tensile strength and anti-fatigue properties before shipping. They are *proved* perfect.

Higgins Quality Springs are equipped with rebound clips. Leaves properly lubricated with special high grade spring leaf lubricant. They never squeak. They never rust. They never leave you in doubt as to their dependability. Safe springs to buy—to use. Immediate shipments.

Ask Your Supply House and be sure to send for prices and Catalog C-1917, showing 500 different styles—also proposition which is certain to stimulate spring sales.

Every Hour

of the day

will save money with a—

WEAVER 20-TON PRESS

THIS PRESS—specially designed for Garage work—can be used to great advantage to perform dozens of operations in your shop other than simply pressing off gears, straightening axles, etc.

Its wide, clean, open construction permits it to be used in a great many ways which are impossible with the ordinary, heavy, bulky type of press. From straightening frames, axles, and similar heavy work down to the most delicate operations such as pressing the pinions off of generators, etc.—there is almost constant opportunity to save money and labor and to perform your work more efficiently.

It Will Attract Trade

Every car owner would prefer to have the work on HIS car performed with a Press instead of with a sledge hammer. HE knows what it means and he will patronize the shop which is equipped to handle work in a mechanical manner.

Enormous Strength and Leverage

Notice that the frame of the Weaver Press is made of ONE PIECE of NINE pound, five inch channel steel—no bolted joints or corners to weaken its construction.

This Press is listed at 20-Ton capacity, but we know of cases where OVER THIRTY TONS PRESSURE have been developed on it, and without any injury whatsoever to the Press.

THE LEVERAGE adjustment for ordinary service is 1500 to 1, but a convenient adjustment is provided which will DOUBLE this leverage when necessary.

Width of frame, 32 inches; perpendicular capacity, 48 inches; BALL BEARING WHEEL for quick adjustment; bronze thrust bearings; 2 inch mill cut screw.

Furnished complete with vise attachment, face plate and special blocking.

A LAMP TEST.

Results Will Be a Guide to New York Motorists.

Tests to determine those lenses and other devices on the market that will bring an automobile's headlamps within the legal requirements of New York State have been conducted by the New York State Motor Federation. Of 38 different articles tested 25 were found to come within the restrictions set, and further tests are to be held on others not passed on. In making the tests, a sheet was placed directly in front of the car at a distance of 75 feet in such a way that a horizontal mark on it was exactly 42 inches above the ground. In the judgment of the committee, the direct beam of light from the lamp was required to fall below this line. Another object placed 250 feet from the lamp and directly in front of it had to be clearly disclosed, these two tests reproducing conditions of the New York law. At a distance ten feet in front of the car and ten feet to the side of the lamp the ground was required to be illuminated by scattered rays from the lens.

The 25 devices which received the approval of the Federation's technical committee follow, with the names of their respective manufacturers:

Warner, Warner-Lenz Co., Chicago.
Letts, Manifold Heater Co., Cortland, N. Y.
Rand, Rand Mfg. Co., Haverhill, Mass.
Glare screen, Palmer Glare Screen Co., Cleveland, O.
Offset, G. T. Sutterley & Co., Philadelphia, Pa.
Stryker, C. L. Stryker, Buffalo.
Ames, Heinze Electrical Co., Lowell, Mass.
Pennock, Specialty Mfg. Co., Minerva, O.
Tilting reflectors, Cadillac Motor Car Co., Detroit.
Star, Lancaster Lens Co., Lancaster, O.
No-glare, No-Glare-On Co., Watertown, N. Y.
More-Lite (clear and amber), L. E. Smith Glass Co., Mt. Pleasant, Pa.
Da Lite, Jeannette Toy & Novelty Co., Jeannette, Pa.
Saferlite, Saferlite Lens Co., New York.
Primolite, Standard Glass Specialty Co., Morgantown, W. Va.
Conaphore (clear and Novial), Corning Glass Works, Corning, N. Y.
Legalite, Legalite Corp., Boston.
Fracto, Crew-Levick Co., Philadelphia.
Mac No-Glare, F. F. MacLean & Co., Syracuse.
Perrin No-Glare, Perrin Mfg. Co., Detroit.
Osgood, Osgood Lens & Supply Co., Chicago.
Omolite, Omolite Co., Jamestown, N. Y.
Holophane, Holophane Glass Co., Corning, N. Y.
Crockett, C. W. & C. H. Crockett, Troy, N. Y.
Rite Ray, Reflex Co., Newark, N. Y.

It will be noted that the list contains the names not only of many well-known lenses, but of devices for controlling the elevation of lamps while using the original lenses with which they may have been fitted by the manufacturer, and devices for breaking up the beams that would offend before they pass through the lens.

If you use an enamel cover for your tires, be sure you put it on right side up. Sometimes we find one put on upside down, which will cause it to hold the rain instead of shedding it.

A New Carbon Scraper.

The Flexible Carbon Scraper Co., 1421 West Washington St., Los Angeles, Cal., has put on the market a novel device for removing carbon. It is claimed these

Flexible Carbon Scraper.

carbon scrapers will do the job as well as it can be done without taking the motor apart. The price is low, and the illustration gives an idea of the character of the device.

A Pleasing Warning Signal.

The old harsh and frightful warning signal for automobiles seems rather on the wane; possibly it is because such a signal is annoying to a good many nervous people. With this in view, the Cathedral Bell Mfg. Co., Baltimore, Md., have designed a signal that is unusually pleasing, although forcible and loud. It is claimed that it attracts attention and does not offend. This bell is unusually simple in construction, the price is very low and it uses only a small amount of electricity.

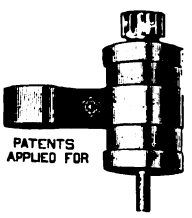
New Bodies for Chevrolet Cars.

The Parry Mfg. Co., well-known vehicle builders in Indianapolis, Ind., have brought out a new type of panel body for the benefit of Chevrolet dealers and others who wish something for commercial use. The fact that this well-known firm has produced it is a sufficient guarantee without further words as to its merit.

A New Spark Plug Tester.

There has long been a demand for a dependable auto lamp tester and a spark tester. These are now supplied by the Jefferson Electric Mfg. Co., 426 South Green St., Chicago, Ill. It need hardly be stated that these devices are unusually essential and desirable in an automobile repair shop. With ordinary care they will last a long time and the price of them is so low that car owners will feel that it would be a matter of economy to have them in stock.

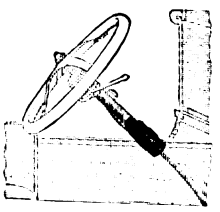
A Big Truck Attachment.



The Commercial Truckmobile Company, 400 Truckmobile Building, Chicago, Ill., are making a truck attachment adaptable to four different sized chasses which is wider, longer and has a greater loading capacity, so it is guaranteed, than anything thus far on the market. It has few parts and is guaranteed for a one and one-half ton load. Strong claims are made for its cheap operation and upkeep. It ought to be a good attachment for dealers to sell not only because it gives a good deal for the money, but likewise because it is simple, unusually strong, and adapted to a wide range of work.

This Is Really a Gasoline Economizer.

A gasoline economizer will soon be placed upon the market which the manufacturers claim is based upon an entirely new principle. It has an unusually desirable feature for commercial vehicles as it does away entirely, so it is claimed, with the necessity of removing carbon from engine cylinders. Strong claims are made for it as to increased mileage for gasoline and also for increased horsepower. The carburetor mantle has been designed and developed along scientific lines and has met with wonderful success in Greater New York, where it was first introduced. There has been developed a mantle for each particular make of car. The devices heretofore submitted to the motoring public have been either those of the screen type or those which permit of a stream of air that is usually admitted through the manifold and requires boring and tapping work. All that is required with the mantle is that the carburetor be dropped down or extended out sufficiently to permit of the attaching of the mantle which is in the form of a gasket, and then the bolts are drawn up and the mantle has been permanently installed. Those who desire further particulars will address Murray-McIntyre Co., 50 Church St., New York.

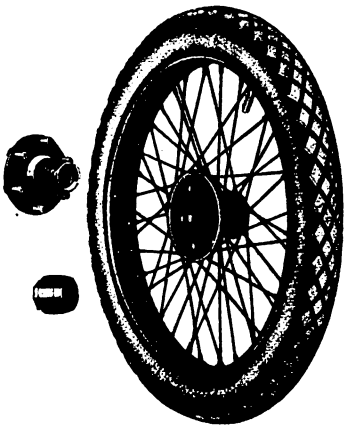


New Ford Car Light.

One trouble in the use of a magneto for lighting Ford cars is that you do not get a good light at low speed. A new electrical invention secures this advantage and it will give a Ford car practically all the lighting advantages of a high-priced equipment and at a cost of

New Lighting Device.

only $2.50. The illustrations give in some measure an idea of the device and how it is mounted. There is no glare and it is a perfect dimmer. The lamps are wired independently and if one naturally goes out for any reason the other



Mounted on the Steering Column.

will continue with the current regulated so there is no danger of burning it out. Those who wish further particulars of this unique lighting system should address the Hastings Mfg. Co., Hastings, Michigan.

New Dayton Wire Wheels.

The Dayton quick detachable wire wheel is a new high grade product, manufactured in Dayton, Ohio. The Dayton Wire Wheel Company is making this wheel under license and they specialize on wire wheels for Ford cars. They have excellent manufacturing facilities, a factory well equipped and an organization of experienced wire wheel men. More tire mileage, easy riding qualities, convenience of changing wheels in case of puncture, the remarkable strength, and the stylish appearance are some of the outstanding advantages claimed for the Dayton wheels. Although this organization only began manufacturing in January, it has been fortunate by having at its head men who are familiar with the wire wheel field and who, by reason of their close association with

Dayton Wheel.

the raw material market, are enabled to secure materials and thereby make immediate and prompt deliveries of the Dayton wire wheels.

To anyone interested, the Dayton Wire Wheel Company will cheerfully and promptly mail literature and any other information desired.

The Bour-Davis Car.

Things are beginning at the Shadburne Bros. plant at Frankfort, Ind. Production on the Bour-Davis car is being transferred from the Detroit plant. Shipments will begin from the Frankfort plant this week. Moving the plant from Detroit to Frankfort was a huge undertaking. Dealers were calling for cars so production could not be interrupted. A small army of men, twenty-two motor trucks and horse trucks were mobilized. Parts, materials and machinery were loaded on trains that were given an express running schedule through to Frankfort. Shipments of cars will begin at Frankfort twenty-four hours after the last cars are shipped from the Detroit plant. Bour-Davis cars are now on exhibition at the salesroom of the Shadburne Bros. Co., 2700 Michigan Ave., Chicago.

A Self-Adjusting Belt.

This belt supplies what may accurately be termed "a long felt want." It is something that has long been needed for automobiles, tractors and machinery generally. It is made of piano wire springs and is absolutely self-adjusting. As a proof of its durability, it is guaranteed for a year, and as guarantees go this is an unusually strong one. This belt is made for about all the different automobiles, and when ordering it it is well to specify the car that it is to be used upon. It is made by the Self Adjusting Belt Co., Watertown, South Dakota.

Worth Sending For.

The Bacon Service, Inc., has issued a booklet for accessory dealers which is designed to show them how to increase their sales. The writer of it knows how to solve the every-day problems of that business and the book is free to any one who asks for it. Write for Booklet D. 7, addressing the Bacon Service, Inc., 151 Grand St., New York.

The Sebastian Lathe Co.
108 Culvert St.
CINCINNATI, OHIO.

TAY-MILLER MFG. CO., Inc.
1714 Cherry Street PHILADELPHIA, PA.

A Great Spot Lamp.

The new law in this and other States involves rather severe requirements for lighting. The Victor Spot Lamp is most satisfactory for these new laws, and the price itself is very low. It is not only beautiful but strong and ought to last a good many years. An advertisement on another page of this issue gives full particulars of its construction and it is guaranteed to give the utmost satisfaction. The firm claims that a better lamp cannot be purchased for twice the price asked for this one. It is very powerful and unsually economical in electric current. If further particulars are required they can be had by addressing the Corcoran Victor Company, Reading Road, Cincinnati, Ohio.

The Despair of Automobile Thieves.

Automobile thieves, of whom there seems to be almost a legion, will find that the new Walker Ke-les Auto Lock will surely put them out of business. There is no keyhole or key and there are over 87,000 changes to the combination. It is easy and quick to operate, cannot get out of order, can be installed quickly and complies with all insurance, fire and police requirements. It has sold like wildfire since it was placed on the market and dealers have found it something that car owners immediately desire when they have once seen it. The profit on these locks is liberal and it is guaranteed in the strongest kind of way. For full particulars, address the Walker Ke-les Auto Lock Co., Chicago, Ill.

Acetylene Welding.

The Imperial Brass Manufacturing Co., Chicago, Ill., have published a new catalogue which treats of welding, cutting, decarbonizing and lead burning. Those interested in these important branches of auto repair work should send to this company and get a copy. Quite likely it will cost nothing provided those making the request do so on their own business letterhead.

Labor-Saving Motor Stand.

The Continental Motor Stand is designed to speed up the assembling and repair of automobile motors. It is guaranteed in every way to save time, meet every requirement of quick assembling, to fit any make of motor and to be easily moved from place to place. It seems to us that it would be a desirable device for every repair shop. It is made by the Continental Auto Parts Co., Knightstown, Indiana.

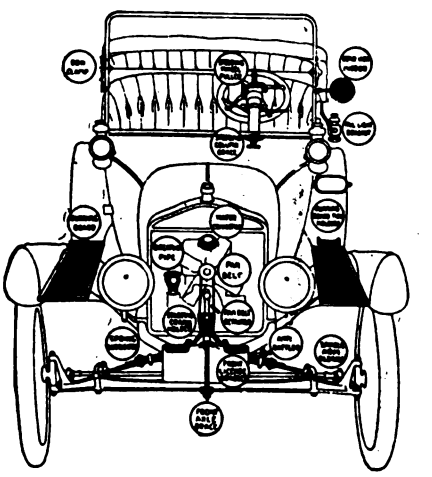
TRADE APCO MARK

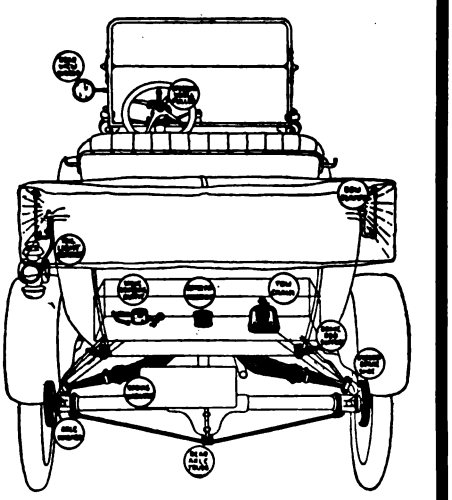
—means "Quality Specialties for Ford Cars" and it is the "buy word" for thousands of *discriminating* Ford owners the world over.

From Front to Back, Back to Front, Inside and Out, the Ford car is a better car when equipped with the Apco "better goods."

As originators and exclusive manufacturers of "Needs for Fords" we are in a position to, and do make products that we are proud to put our name on, and when you see Apco on the outside of a box you can gamble on finding quality on the inside.



Our prices are lower in most cases than the inferior goods, and the reason we can combine high quality and low prices, is because we produce more of this material than any other five concerns in the country.



DEALERS

There is nothing that shows better profit than the Apco line, especially to those dealers who value the satisfied customer as an asset.

Every Apco product is packed in an individual box and when they are on your shelves they look like real merchandise.

Get busy now, and when a customer asks for an Anti-Rattler, reach up on the shelf for an Apco, instead of down into a nail keg for a nameless, often useless, imitation. Our Catalog and Discount Sheet should be on your desk now, and remember Apco goods are sold by Jobbers only in one hundred and twenty-eight cities in the United States.

APCO MANUFACTURING COMPANY, Providence, R. I.

SUNDERMAN
Vacuum Carburetor

$5

F. O. B.
Newburgh

$6.50
other than
Ford or Metz

On September 1st this carburetor will cost you more. Why not send your order in at once? You'll save money and increase the available supply of gasoline—by saving from 30 to 50% with a Sunderman. ACT!

The Price Advances September 1st

Advancing material and labor costs compel us to raise the price of the Sunderman Carburetor.

The one-inch model, ready for installation on Ford and Metz cars will be $6, instead of $5, on September 1, 1917. The one-inch model with elbow and regular fittings for standard cars will be $8. Special jobs at slight advances to cover cost of manufacture.

This announcement gives dealers and car owners an opportunity of getting their orders in at the old prices. In this way we give them the benefit of the Sunderman policy of fair treatment to all customers.

The advance is slight—scarcely enough to cover the raw costs of production. We have consistently refrained from capitalizing the exceptional qualities of the Sunderman Carburetor by putting a high price on it.

We held off as long as possible—until a stubborn material market and persistently increasing labor costs compelled us to advance the price.

The **economy** of the Sunderman—and its marvelous efficiency on every test of a carburetor long ago justified us in charging a price commensurate with its worth. We have never done it.

When a carburetor saves from 30 per cent to 50 per cent of gasoline on any car, its worth is usually reflected in a high price.

The Worth of a Sunderman Is Shown in Service—

the price has always been, and the new price will be, simply the cost of manufacture plus a small profit. We look to the volume of sales, rather than to how much each sale can make for us.

In these days of conservation of resources, it is the patriotic duty of every car owner to save gasoline. The Sunderman Carburetor does it without laying up the car—it gives many more miles per gallon—sometimes **double.** Every motorist owes it to himself, to national economy and to his fellow owners to let us prove our economy claims.

Therefore, send in your orders NOW
Before the advanced price becomes effective.

Like Sugar in a Grocery Store

BUMPERS have come to be as staple to the Dealer in Automobile Accessories as is Sugar to the Grocer. Bumpers are as necessary to the safety of an Automobile as sugar is to the table.

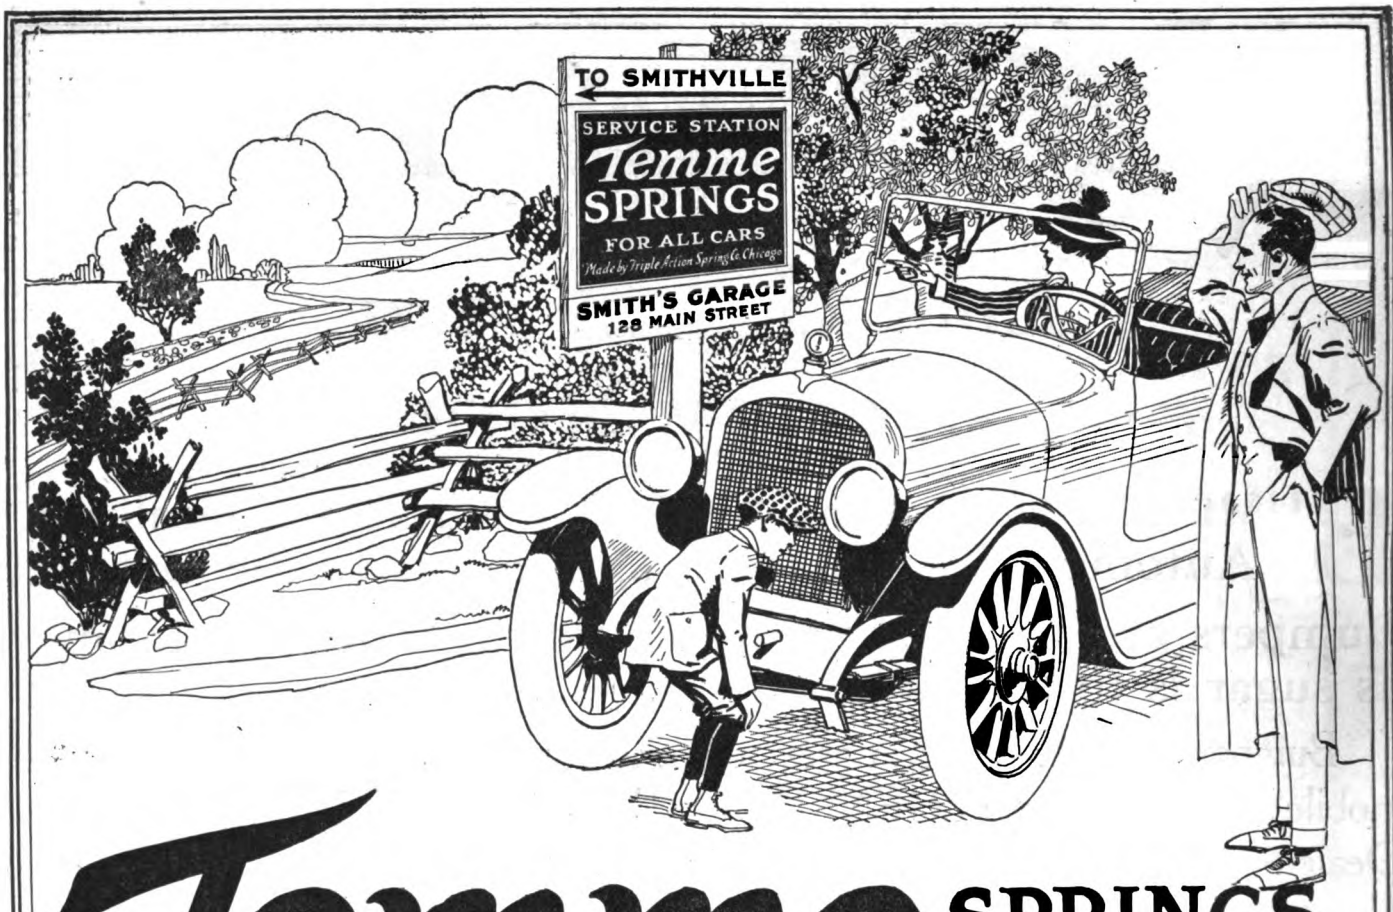
Bumpers, besides being in great demand by ALL CLASSES of Automobile Owners, bear a GENEROUS MARGIN of PROFIT for the Dealer.

HALLADAY Bumpers are at the very top of the Bumper field, peerless in their gigantic strength, their scientific lines of refinement and in their beautiful finish.

There is a HALLADAY Bumper made to fit every make of automobile on the road and the dealer handling the HALLADAY Line is in a position to command all the Bumper trade in his territory.

Add to this that HALLADAY Bumpers are nationally advertised in the leading automobile publications of the country and you have the ideal Bumper Line.

Live wire dealers looking for a live wire line of Bumpers and other automobile accessories, just pin this advertisement to your letter-head, send it along to us, and we'll give you full particulars about the "Profit Bearing Line," made by the House of Halladay.



Don't Procrastinate. Do This Today.

Temme SPRINGS FOR ALL CARS

THE picture tells the story. Are *you* the Mr. Smith of Smithville? Are *your* highway signs on all your roads?

Do all the lame cars drive to *your* door for Temme Springs and other things?

If *you* are not Smith, who is? Or who will be? That's the question.

And in most good towns it will be answered soon. For Temme Springs and Temme's Triple Action Service are known to be *as good as gold.*

Hundreds of repairers, who have "banked" on Temme and never lost, are putting up these Temme highway signs today.

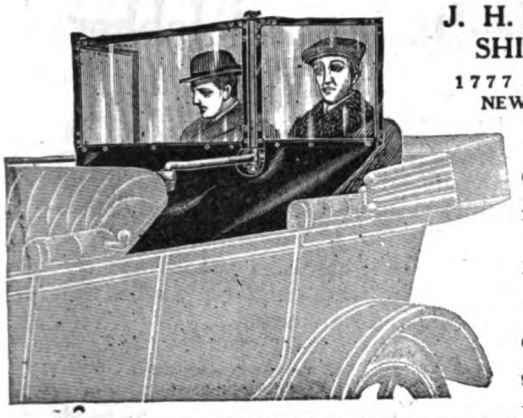
These signs *will* bring in business. Temme has tried them, so he *knows.* And now he offers *you* what won for *him.*

Temme Springs *"for all cars"* means just what it says—for all cars *since 1902.* Test us by naming the spring you need. Temme Triple Action Service will have it on the way to you the same day.

"For all cars" means *designed* for all cars to factory specifications. And so good are Temme Springs—so prompt the service—so fair the prices—that dealers in *all* cars now buy from Temme *in preference* to the car maker.

You need these springs, this service, these signs. They will make you money, bring new business, help you build the good reputation you are after.

If you delay you may lose this exclusive proposition. Write or wire us now, saying: "Send Temme Spring Service Station proposition at once."



JOHNSON
Shock Absorber

This is to remind you of the new model of the famous Johnson Shock Absorber—made by us. The only cure for a hard riding car is a pair of Johnsons. Temme Spring Service Stations make good money on them. Write now for our new proposition.

Mr. Garage and Repair Man—LISTEN—Dealer and Jobber

IT MAY SOUND TOO GOOD—BUT! NEVERTHELESS IT'S TRUE.

PACKED, WEIGHS 5 LBS.

Think of it: A "Multiple" valve grinder—grinding **Four (4) Valves** of a Ford motor at **One Time** by a single back and forth movement, **Saving** 50% in time. Satisfying your customer more at less expense and **More Profit** to yourself.

Yes sirie it's wonderful—so it has been proclaimed by thousands of satisfied users, who claim it to be the greatest labor saving device on the market.

1. **Because it will grind—Two (2) intake and two (2) exhaust valves at one time.**
2. **A boy can grind in a set of valves more perfectly with our "Multiple" than it is possible for a skilled mechanic by hand with the best of tools.**
3. **Insures a more perfect seat than hand grinding—account of being bolted down with cap screws and held central and in alignment by a single back and forth movement of handle the valves are rotated 1¼ revolutions and automatically lifted from their seats and reversed 1¼ revolutions, thereby adding greater efficiency to the motor and more satisfaction to the customer.**
4. **Saves disputes of customers account of too much time spent on job beyond your control—due to the ancient method of hand grinding.**

No mechanic necessary to do valve grinding with the "Multiple." A boy can do this in ½ the time, better and more perfectly, than is possible for a skilled mechanic by present day method.

No drilling or tapping necessary—One minute and grinder is fastened ready for operation. Being held central and in alignment it will insure a better and more perfect seat, adding greater efficiency to the motor and more satisfaction to customer. *WRITE FOR PARTICULARS.* AGENCIES OPEN.

UNIVERSAL PURE AIR PUMP CO.
1607-11 Prairie Avenue CHICAGO

900 Pages instead of 824 **1918—SIXTH EDITION** 3362 Illustrations instead of 2000

Still $3.00 **Dyke's Auto Encyclopedia.** Still $3.00

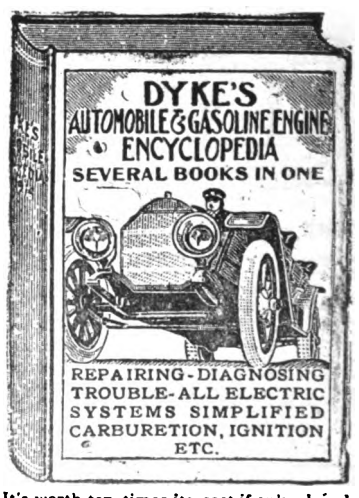
Entirely re-written, hundreds of illustrations and many new subjects added. Practically a new book. A non-technical treatise with simplified illustrations on Construction, Operation, Repairs and Adjustments, Cares and Troubles of the Automobile.

There are 50 **Instructions**—Simplified and practical.
3362 **Illustrations**—the kind you understand at a glance.
2 **Supplements**, part printed in two colors, treating on the construction, operation, repairing and adjusting of the **FORD and PACKARD**—tells how to make a Ford do 60 miles per hour; how to get more mileage per gallon; how to convert into a truck, racer, fine point adjustments, etc.
775 illustrations and 279 pages on **Electric Ignition, Electric Starters** and **Generators**, etc.
51 pages and 79 illustrations on the **Delco** system alone.
60 pages and 254 illustrations on **Adjustments, Tests**, etc., of leading **Electric Systems.**
154 pages and 1189 illustrations on **Repairing.**
27 pages and 180 illustrations on **Tires** and **Tire Repairing.**
44 pages and 119 illustrations on **Carburetion.**
89 pages and 291 illustrations on **Engine** and **Parts.**
16 pages on **Digest of Troubles.**
6000 lines to the **Index.** This is a feature worth noticing, as it means a ready reference on everything pertaining to motoring. **Index** begins on **colored** paper, easy to refer to.
Dictionary is also included, which gives the meaning of motoring terms.
Inserts: There are five—printed in colors. New features you never before saw or heard of in one of the inserts.

You must see this SIXTH Edition in order to appreciate just how complete a book it really is—Order N-O-W.

Price—Although a much larger and better book the price for the present remains **$3.00** (or **$3.32** prepaid).

How to Become an Expert Automobile Mechanician



The quickest and cheapest, but BEST way, is by studying Dyke's Automobile and Gasoline Engine Encyclopedia.

It is a practical, simplified instruction on everything you want to know and OUGHT to know about motoring.

First you learn the principle of construction of each and every part of a car and engine—then the variance of construction—then the adjustments and repairs.

You learn how to diagnose troubles in a scientific manner. Step by step you advance until you are a *real expert* on timing the valves and ignition, repairing and adjusting. You learn the carburetion subject so thoroughly, you can adjust any make.

You will like this book, in fact we will guarantee you would not sell it for three times its cost if you could not get another.

It's worth ten times its cost if only placed on the shelf and used as a reference.

You will also understand Aviation, Truck and Tractor Engines as well as Auto Engines when you complete this book.

Beware of Imitators—this is the *original, simplified* book on REPAIRING, ELECTRICAL SYSTEMS, TROUBLES, Etc. It is the only book in the world combining all these subjects under one cover. Why get three—or four books?

Mr. Dyke published the first practical Automobile Book in America.

STRANSKY'S FUEL VAPORIZER

Price, $3.00. Sold on a Strictly Money-Back Guarantee.

Dealers Wanted Everywhere

Several agents wanted for all open territory, best agency proposition on earth today. We furnish proof of state agents making over $500.00 per month above expenses.

Reference, First National Bank, Pukwana, S. Dak.

Twenty Thousand Sold!

Twenty Thousand Satisfied Customers

Sample $3.00, send bank draft, money order, or your check will do if you add 10c for exchange. Money plus postage returned, if not satisfactory.

YOU are to be the judge and jury; if not satisfactory, return it and get your $3.00 plus postage by return mail.

There is absolutely no power to gasoline unless it is vaporized.

The average carburetor will only vaporize from 50% to 75% of the fuel.

The Stransky Vaporizer Will Vaporize Close to 100%

If the Stransky Vaporizer vaporizes from 25% to 50% more fuel, you will get 25% to 50% more mileage—more power—more speed —and no carbon.

The Stransky Vaporizer works automatically, no spring, diaphragm or shutters, only one working part, the steel ball valve. It is made entirely of brass and steel, and guaranteed to last a lifetime.

No holes to drill or tap—no special tools needed — any farmer with an ordinary wrench can attach one in five minutes time.

STRANSKY MFG. CO.
Stransky Block, Pukwana, S. Dak.

United States Post Office, Pukwana, S. Dak.

I have been carrying the rural mail out of Pukwana, S. D., for over one year, using a Ford car. I have averaged 3 gallons on the two routes each trip. Since putting on one of the Stransky Vaporizers, I made the two trips on 2 gallons, or the saving of 33⅓ per cent. I can now make hills on high that I could not make before. I have paid for the Vaporizer several times in the saving of fuel. My motor never overheats, which feature alone is worth many times the price of the Vaporizer. I would not take $100 for it, if I could not get another.

J. C. CROOKER.

Richmond, Va., June 27, 1917.

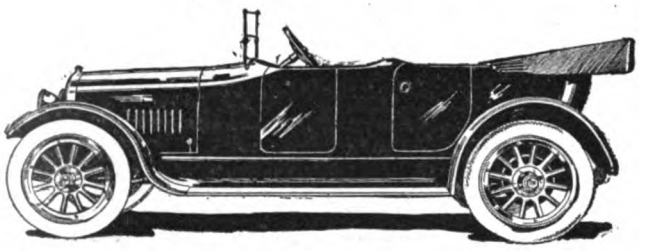
J. A. STRANSKY, Pukwana, S. Dak.

Vaporizer received, installed in jitney service last week, splendid results, absolute saving one-third gasoline, increased power and speed one-third, does all and more than you claim for it. ship one hundred at once, writing you fully today.

R. C. SOUTHERN.

The Whitbeck National Bank, Chamberlain, S. Dak.

To Whom it May Concern:



This will introduce Hon. J. A. Stransky, an ex-member of our State Legislature and the Democratic candidate for Governor of South Dakota, four years ago; whom we have known for nearly 30 years, from a young man up, and who resides at Pukwana, S. D. He started with nothing but his fists and now is in good, comfortable circumstances and is known for his square and honest dealings in live stock and telephone lines. What John Stransky says can be depended on and I take pleasure in giving him this letter.

A. C. WHITBECK, President.

"THE CAR AHEAD"

Results

IF WE WERE ASKED to give the average motor car buyer **one** bit of advice, it would be "DON'T GO INTO TECHNICALITIES."

HIGH PRICED ENGINEERS are paid to solve problems of mechanical construction for you. The man who exhibits a **little** motor car knowledge is the sort of buyer that the clever automobile salesman is looking for.

GET DOWN TO ESSENTIALS at once. Results are what **you** want. They are the **only** things that count.

CERTAIN THINGS THERE ARE, however, which you **only** can judge.

PERFORMANCE: Make the car show you that it has power - easy, smooth, flexible power. Take any ordinary hill on high—but **don't** put it to unreasonable tests just because some "stunt" demonstrator down the street does so with his. Try out the car where **you** will drive it—not where you won't.

COMFORT: Demonstrate the riding qualities over rough roads. Naturally in your usual driving you won't look for them, but unfortunately they can't always be escaped. **Is there plenty** of leg room in the front seat? Can three ride comfortably in the rear seat of the touring car, or two in the "Get-chummy" seat of the roadster?

DURABILITY: Assuming that the performance and comfort meet your requirements, find out how long they will last. Here, you will have to take somebody's word for it. Ask your friends who own cars of the same make. Secure lists of owners from the dealer and make your own investigations. Hire yourself as your own purchasing agent temporarily and make that purchasing agent understand that he is spending upwards of $1200.00 of **your** money.

APPEARANCE: The general lines, the upholstery, the painting and finish, the refinement of details must appeal to you if you are to enjoy a happy purchase. As much so as in buying a new gown or suit of clothes. Insist that insofar as it does not interfere with mechanical construction that **your** motor car reflect your personality. Just because the manufacturer likes to paint cars green is no reason **you** shouldn't have one in a light tan with gold trimmings if you want it.

We could go on indefinitely; enumerating price, service, stability of the manufacturer, etc. We could **tell** you how dollars that you will never see but only later realize have been built into the Pilot Six Forty-five. But we would rather **show** you.

THIS IS WHAT WE ASK: **In a practical dollar-and-cents way compare Pilot Performance, Comfort, Durability, Appearance and Individuality with any motor car that sells for within two hundred dollars more.**

The Car that Produces Results for the Owner Produces Profit for the Dealer

PILOT MOTOR CAR COMPANY

RICHMOND, INDIANA, U. S. A.

To Manufacturers of Ford Accessories and Attachments.

The Accessory Jobbers have endorsed the great National Exposition for Ford Accessories which will take place at the Chicago Coliseum, September 22nd to 29th, expressing their approval in hundreds of letters.

The National Exposition of Ford Accessories is staged at a period that will afford the individual jobber ample time to determine and list the articles for his next season's catalog. This advantage has created the feeling of enthusiasm and interest with which the jobbers view this coming show.

The Exposition is to be run on a manufacturers' co-operative plan. It will stimulate a healthy trade through the educational means afforded only by a National Exposition of this character. Already one-third of the floor space has been sold.

Manufacturers of Ford Accessories and Attachments are advised to secure space for the exhibition of their products NOW.

Electrical Repairs Bring the Big Profits!

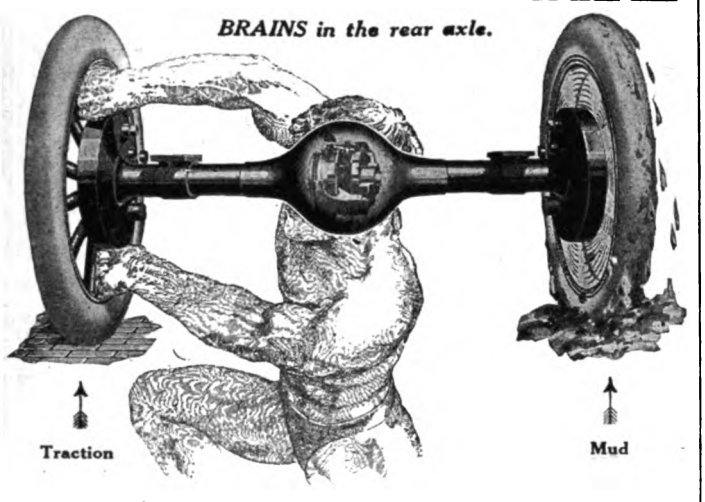
If you cannot repair electric starting and lighting equipment intelligently, your customer will go elsewhere for this service. He will take the rest of his trade with him. There is more money in electrical repairs than in any other department of the garage business. The demand is enormously increasing.

Weston Model 280 GARAGE TESTING INSTRUMENT

is the best, the most reliable and therefore the cheapest electrical equipment for you. It enables you to determine promptly and accurately the condition of the electrical equipment of any automobile, just where the trouble is and just how to remedy it.

Write for our *Special Proposition.*

Weston Electrical Instrument Co., 2 Weston Ave., Newark, N. J.



23 Branch Offices in the Larger Cities.

BAILEY

NON-STALL

DIFFERENTIAL

BRAINS in the rear axle.

POWER to the wheel that can use it.

A Fundamental Necessity For Every Car

The Bailey Non-Stall Differential *corrects a basic weakness.*
Old style differentials let the power go to waste by sending it to the wheel that does not have traction.
This causes practically all skidding, slipping, stalling, spinning and side-swaying. It is an enormous unnecessary waste of power and tires, and often causes accident troubles and expense.
The Bailey avoids all of this.
With the Bailey no power goes to waste, but *all* of it is used *properly.*
It makes you master of all road conditions.
Anybody can install it quickly. It can be fitted to any rear axle.

Owners and dealers should write us for complete information.

Bailey Non-Stall Differential Corporation, Chicago, Illinois, 1124 Michigan Ave.

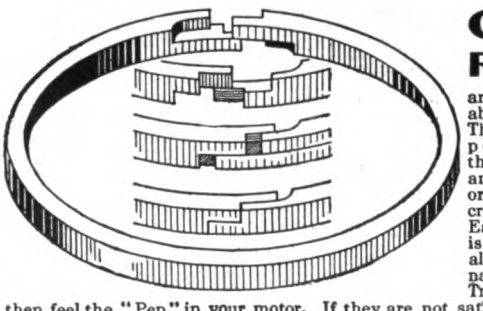
ELIMINATE DANGER
WHEN CRANKING YOUR FORD

Every time you crank your Ford Car you are courting disaster in the form of a broken, sprained or badly bruised arm or wrist, on account of pre-ignition, either thru forgetting to retard the spark or intentionally advancing it beyond the safety point to insure continued running.

THE BILL AUTOMATIC SPARK RETARDER

is an absolutely automatic device, which can be installed by anyone, and which once installed requires no attention whatever. BILL then retards the spark to a point of absolute safety upon engagement of the crank and then upon the first power stroke of the motor advances the spark to the running point.



This is a fine Dealer Proposition as they sell on sight. Retail price is $3.50.

Write to-day for details and dealer prices.

THE RED ROAD BOOK

250 Pages. Price, $2.00

—and—

THE AUTOMOBILE DEALER AND REPAIRER

$1.00 a Year

BOTH FOR $2.00

A great many of our subscribers will be glad to know that we have made arrangements with the Bullard Co., of Boston, publishers of the "RED ROAD BOOK," on such favorable terms that we can offer this admirably arranged book, size 9¾ x 9¾, and comprising 250 pages, in connection with the Automobile Dealer and Repairer for a year, for $2.00, which is the regular retail price of the book.

In other words, by subscribing to the AUTOMOBILE DEALER AND REPAIRER, the subscription rate of which is $1.00 a year, you get the "RED ROAD BOOK" AT HALF PRICE.

We don't know of any better book than this on the market. It is bound in flexible cloth, and comprises road maps of the following states:

All of the New England States	**Pennsylvania**	**Virginia**
New York	**Maryland**	**West Virginia**
New Jersey	**Delaware**	**District of Columbia**

These states are largely patronized in the Summer by tourists from all over the country, who like to visit the Catskills, the Adirondacks, and the White Mountains. The "RED ROAD BOOK" also gives maps of that portion of Canada reached by routes from Northern New York, Northern New England and Northern Maine.

It further gives 153 city street maps, to which are added road distance tables, ferry tables, and the necessary population and location indices for all towns.

Reading route matter in connection with the principal routes is tersely told, and will be printed in black, and their reverse routes printed in red, to avoid confusion.

The aim in the production of this work is simplicity. Too many automobile route publications attempt so much, that in their efforts to be "complete" they become "confusing." The publishers of this work say that many years of motor travel and the observations of others lead them to the opinion that once out of the confusion of a city's streets, on the broad highway, the need is less for the detailed, must-be-closely followed printed words, comments and instructions of the path itself, but rather the need is for the accurate knowledge that the road to town A and thence to town B is of "automobile goodness." and that it proceeds via this and that village, this or that side of a lake or a mountain, with crossing railroads, or paralleling trolley lines, as a check on location.

Thus is one free to carry out his original purpose; namely, to see the country, with this instruction book.

If with such maps as are shown in this road book, one sees that they are to pass within a few miles of a well-known and picturesque lake, or historic hamlet, or perhaps desire to go "across country," a good road map is the best aid for this free lance mode of travel.

A new edition of this road book is now being prepared, and will be corrected right down to date, and will contain much new material. The book will be ready for delivery from the first to the fifteenth of April.

All orders sent to us will have prompt attention just as soon as the book is issued. In case you have already renewed your subscription, a Red Road Book will be sent on receipt of One Dollar Address:

BUNTING BRONZE

CORED BARS

Bunting Bearing Metal is overwhelmingly favored—because we have steadfastly adhered to an ideal which subordinates everything to the prime question of quality.

Beyond the shadow of a doubt, we can suit you to a "T"—for our Cored Bars are made of the world's best—yes—very best phosphor bronze. Over 300 of the largest manufacturers of machinery, engines and motors have adopted it for use in their products and they are more than satisfied.

If you, too, wish to use Bunting Bronze, the wise practical expedient way would be to write us a letter today—why not—it's for your own good.

PIERCE Governors

FOR FORD CARS

The owner's hand controls the speed of every Pierce equipped Ford truck or delivery wagon, no matter when or where it is driven. It makes no difference who the driver is, he cannot exceed the speed for which the governor is set—and the owner decides the speed.

A Pierce Governor don't cripple the motor when heavy loads, steep grades, or slippery traction demand extreme power. It is the only governor made that will control the speed of a Ford truck, and leave the motor entirely free in reverse and low gears.

Stop fast driving and you eliminate 75% of all collisions and accidents reduce repair costs one-half—and make tires wear longer. Pierce Governors pay for themselves a dozen times a year.

METAL FLAGS and EMBLEMS Are What the Autoist Wants

No. 8006. 3¼" High. 5" Wide.
Gold or Nickel Finish
ENAMELED COLORS - - LIST, $2.00

The fifty-seven varieties of flags and emblems of fabric, rubber, silk and what-not have come, been seen, and have failed to conquer.

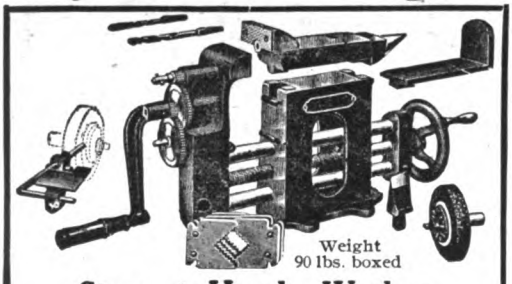
There is a demand that will not be denied for flags that will not fade, that will not fray, that wind and weather will not affect, that will look as well weeks after they are mounted as they did the first day they appeared on the radiator cap or front.

There is only ONE answer—Metal Flags and Emblems. Our catalog includes a score, from the lowest priced, upwards to the large, elegantly embossed, gold plated and finely enameled emblems fit to ornament the finest car.

No. 8597. 4" High. 5" Wide.
Embossed on Solid Heavy Metal
ENAMELED COLORS - - LIST, $2.35

We show two above; "America First" is by long odds the most popular emblem ever made for the radiator cap. The favor is absolutely universal, and it is seen on every type of car from the lowest priced up.

The "Allied For Humanity" design is handsome, very striking, and retails at a most reasonable price.



Our catalog and new supplementary circulars will show you many more proven sellers that will help to fill up the profit side of your ledger. Liberal discounts from list prices afford you a margin worth while.

We furnish electros, display stands, etc.

THE ART METAL WORKS, 7-15 Mulberry Street, NEWARK, N. J.

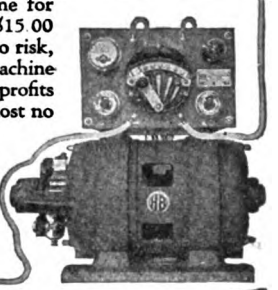
Big Profits in H-B Battery Charging



There is a big money-making opportunity for you in recharging auto storage batteries. Owners of H-B Battery Chargers are clearing from $20.00 to $60.00 a month; some have made as high as $139.50 net profit in the first month. What others are doing, you can do.

The H-B Battery Charger requires no electrical or mechanical knowledge. You can connect it right on to the wires already in your garage, using either direct or alternating city current. It will recharge any make or size auto storage battery quickly, successfully and profitably.

$15 Puts This Money-Maker In Your Garage

Balance in ten monthly payments of $15 each, which your earnings should easily meet and give you a good profit besides. One to seven batteries charged at a time. Average charging cost 12c. per battery. Autoists pay 75c. to $1.50. Profit at least $4.50 each capacity run.

Tear out this ad. Mail it with your name for full particulars, or send initial payment of $15.00 with this ad. to order on trial. You run no risk, as under our guarantee you can return the machine if it is not absolutely satisfactory. These profits are yours if you want them. There's almost no expense to you. Don't put it off.

Attention, Mr. Garageman!

ROMORT TIRE TESTER ATTACHMENT

PRICE, $1.50

This is a device for attaching your gauge to Romort Automatic Air Valve, and gives the service station a permanent holder for its gauge, ready for instant use by the public, eliminating the necessity of loaning gauge to operator, who three times out of five will drive off with your gauge in his pocket.

Attached to Romort Style A Automatic Valve

Simply screw your gauge into this holder and you have a tire tester and tire inflator combined in one, and the old trouble of losing gauge is forever over.

Every garage with free air should be equipped with the Romort Automatic Air Valve and Tire Tester Attachment.

The above price includes the Attachment only.

CAUTION—When ordering, state whether for Style A or B Valve.

IT MAY BE YOUR TURN NEXT

TO MEET WITH AN ACCIDENT ON THE ROAD.

It may also be a case of life and death to have the materials at hand for prompt treatment. We have recently made arrangements for a First Aid Case for emergencies especially for the readers of the AUTOMOBILE DEALER AND REPAIRER.

No orders can be filled from the State of New York, it being against the law for anyone to sell medicine who is not a registered pharmacist.

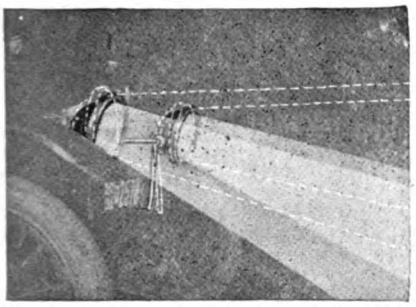
This case is made of heavy Bessemer Steel, size 11½x5½ and 2¼ inches deep, finished in Black Baked Japan and fitted with a strong instantaneous snap. It is strong enough to resist injury to the contents through accident or dampness.

The contents have been carefully selected to supply the needs in an emergency, before the doctor comes. All gauze, bandages and cotton have been prepared in aseptic laboratories under the same rigid inspection as those supplied to the United States Army and Navy.

The contents of this case consists of:—1 "First Aid to the Injured" Instructions. 1 Yard plain Sterilized Gauze for dressing large wounds. 10 Yards 2-inch Sterilized Gauze Bandages for dressing cuts and bruises. 10 Yards 2½-inch Sterilized Guaze Bandages for dressing cuts and bruises. 1 Package Sterilized Absorbent Cotton for pads and dressings. 1 Box Carbolic Salve for burns, sores, insect bites, etc. 1 Yard 1 inch Zinc Oxide Adhesive Plaster for retaining dressings and covering small wounds. ½ Ounce Tincture of Iodine, an antiseptic for immediate use on all wounds and abrasions. ¼ Ounce Spirits of Ammonia for use in case of shock, heart failure and faintness. ½ Dozen Safety Pins.

The retail price of this outfit is $2.50. We have made an arrangement with the manufacturers of such a liberal character that we can supply this outfit with a subscription to the AUTOMOBILE DEALER AND REPAIRER for a year, for the regular price of the outfit, $2.50.

In case you have already subscribed for this year, we will send you one of these outfits, postage prepaid, on receipt of $1.60, which may be remitted by check, money order, or in any convenient way.



Every subscriber to the AUTOMOBILE DEALER AND REPAIRER should have one of these outfits. It may mean the saving of your own life or the life of some friend. ***ORDER AT ONCE AND THEN YOU WON'T FORGET ABOUT IT.***

ALL YOUR GAIN

It Is a Hobby with Some Men to See How Good They Can Make a Thing

IN THIS CASE IT HAPPENS TO BE THE

TESTITE PISTON RING

And a very—VERY Good Ring It Is

Made with an eye single to absolute technical precision. You would hardly imagine it possible that such a supposedly common thing as a piston ring could be made so uncommonly good.

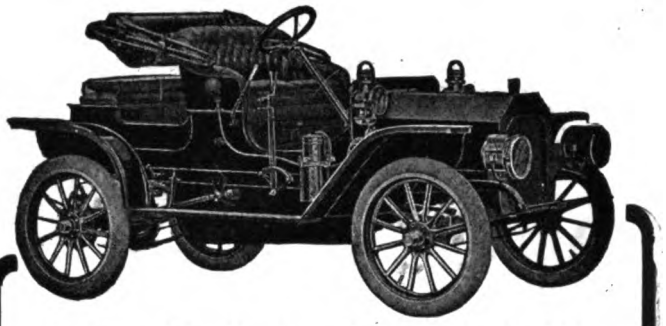
Testite Piston Rings are made in all sizes to fit all motors.

Testite Piston Rings save gas by utilizing the entire fuel charge in the production of power. There is no waste. No loss of power, no waste of exploded gases past piston ring openings.

Testite Piston Rings are a boon to marine, and also to aeroplane motors, where the highest compression is so vitally important.

Testite Piston Rings make your motor measure more power, make it more responsive, and though the highest in efficiency, are the lowest in price for piston rings of their character.

Every ring is inclosed in a separate envelope with directions for installation and are packed twelve in a box for the trade.



Our literature, we believe, treats the Piston Ring question in an intelligent manner—learn more—write us—today—that's better than forgetting it.

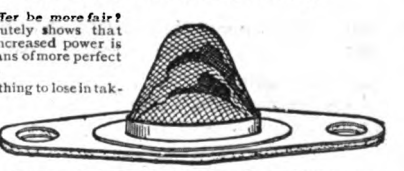
GASCO

GASOLENE ECONOMIZER

NOW—IT'S UP TO YOU!



Truth is never crushed to earth if given a square deal. Pin a dollar bill to your letterhead—mail it to us and prove Gasco's distinguishing traits.

First, determine the speed of your motor while idling and with the throttle all the way down.

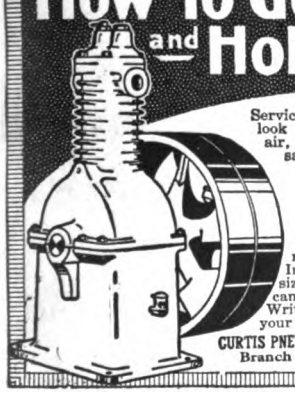
Then unbolt the carburetor flange from the intake manifold and insert the Gasco as if it were a gasket, tighten up the bolts and start up the motor.

If the motor doesn't run faster than it did before, just send the Gasco back and we'll refund your money.

Can any offer be *more fair?* This test absolutely shows that with a Gasco increased power is obtained by means of more perfect fuel combustion.

You have nothing to lose in taking advantage of this offer, and you can readily prove for yourself that Gasco will save its cost in a short time in the saving of fuel, besides adding power, reducing carbon, and preventing fire due to backfire.

Thousands sold—one large concern purchased 3200.



Dealers everywhere find it a quick seller and a good profit-producer. Our sales plan calls for a small investment and gives a quick turnover. Write today for particulars.

Use G. T. D. Spiral Fluted Reamers

G. T. D. Reamers really *smooth* the walls of the hole because they are built with the left-hand spiral.

This construction causes them to produce a fine shearing cut and obviates all tendency to "hog-in," even when there are flaws and seams.

The result is a perfectly smooth, polished hole like that shown in the illustration.

This is only one of many G. T. D. tools. Ask for Catalog No. 37 showing complete line of Taps, Dies, Reamers, etc.

"THE RETURNS"

that we get from our Advertisement in "THE BLACKSMITH & WHEELWRIGHT"

— ARE GOOD — VERY GOOD !!

NO matter what kind of Auto Equipment you manufacture, you ought to advertise it in "The Blacksmith and Wheelwright." These "Smiths" and "Wrights," all over the country are now Repairing Autos and Selling Auto Goods. They seldom or never get a look at an Automobile Journal—but they do swear by every printed word they see in their tried and true friend, "The Blacksmith and Wheelwright." They are on the keen edge to know what auto equipment men have to sell—and they buy.

"The Blacksmith and Wheelwright" is the oldest journal of its kind in the world, having been published for more than 37 years under the same ownership and management, and recognized as a leader in its field.

YOU CAN'T BEAT IT!

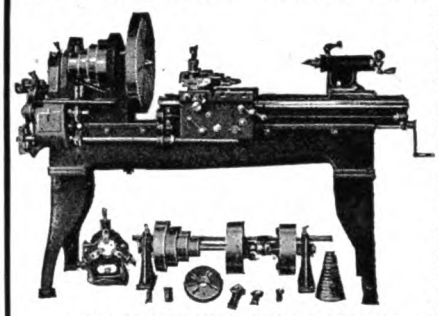
The Famous **"Little Giant" Starter**

FOR FORD CARS

A Mechanical Starter OUT OF SIGHT

Entirely within the hood. Everywhere recognized to be *superior* to all other mechanical starters made for Ford cars. Easily installed, **safe, simple, durable, dependable, and always ready.**

First Cost is Whole Cost



Fully Guaranteed Live Agents Wanted

For Full Information, Address

THE LITTLE GIANT STARTER CO., CANTON, OHIO

THE UNIVERSAL GARAGE LATHE

IS OUR 14-24" SLIDING EXTENSION GAP LATHE

Saves investing in a large expensive lathe. Swings 14½ in. over top bed and 24 in. through gap. The 7½ ft. machine takes 8 ft. between centers.

Cuts right or left-hand threads, and can be furnished with transposing gears for millimeter threads.

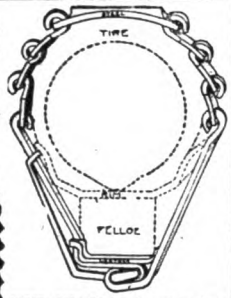
Taper attachment, milling attachment, and other accessories if wanted.

Machine is strong, rigid and accurate, has 2⅛ in. spindle with 1⅛ in. hole through same. There are six quick change geared feeds and other new features. Great range and value at a reasonable price.

JUST THE THING FOR GARAGES AND REPAIR SHOPS

Send for New Literature and Prices.

Barnes Drill Co., Inc. 1907 818 Chestnut St., Rockford, Ill., U. S. A.



Builders of the All-Geared Drill

Hang on to your old tires. They will last as long as you live if covered with steel. **The Kimball Steel Protector** makes **Blowouts, Punctures** and **Rim Cuts** impossible. A few sections will hold any old blowout. Tires as flexible as ever.

Special inducements to those in new territory.

MUD CHAIN can be put on in a jiffy with one hand while standing on the run board. If you get in a mud hole you will laugh out loud. Hook the ends together and pull the little lever and they are on tight. Good for blowouts.

KIMBALL TIRE CASE CO., 174 Broadway, Council Bluffs, Iowa

SEE THAT GROOVE CONTROLLING THE OIL?

LISTEN!

The groove full of oil forms a dam. Gas cannot get down, oil cannot get up. That's why motor has more power, no carbon.

ISN'T THAT A REASON?

"NO-LEAK-O" RINGS GUARANTEED SATISFACTORY, OR MONEY BACK

Don't rebore cylinders.

"NO-LEAK-O" restores power when others fail.

FOX TYPEWRITERS

Factory Rebuilt Like New at $65.

The word "rebuilt" has been abused and misused until it has become a meaningless trade term. When we rebuild a Fox Typewriter we take it all to pieces, re-nickel the nickel parts, re-enamel the frame and replace all worn parts with new ones. The same men who originally built the typewriter do this rebuilding **and do the work just as good.**

50% NEW PARTS AND 3 YEARS GUARANTEE

We offer a rebuilt Fox Typewriter, Model No. 24—*just like new*—for $65.00. These have standard carriages taking paper 10½ inches wide, any kind of keyboard, any kind of type, rubber covers, tabulators, back spacers, two-color ribbons, and are complete with instruction books and cleaning outfits.

Send us any amount you can spare, **from $1.00 up,** as a first payment, and pay the balance $5.00 monthly. Or, send $61.75 all cash. If $10.00 or more is sent with order we will include Free our $4.50 Solid Oak Typewriter Table. Transportation must be paid by the purchaser.

Please order direct from this offer, mentioning Automobile Dealer and Repairer for January. State price you wish to pay and enclose any amount of cash you can spare.

FOX TYPEWRITER CO., 6201-6211 Front Ave., GRAND RAPIDS, MICH.

Pay $5.00 Monthly

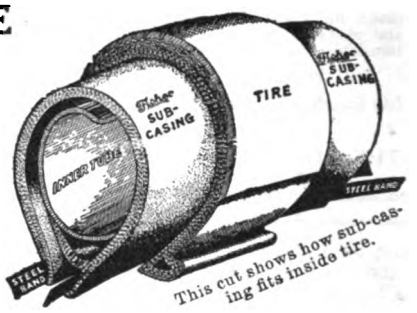
THE Fisher PATENTED "RIM-GRIP" SUB-CASING

MORE MILES PER TIRE
LESS TIRES TO BUY

THE BLOWS THAT YOUR TIRES RECEIVE, WHEN YOU STRIKE OBJECTS IN THE ROAD, LEAVE WEAKENED PLACES IN THE FABRIC.



A TIRE IS AS STRONG AS ITS WEAKEST PLACE

These weakened places are hard to detect now, but will result in blow-outs later.

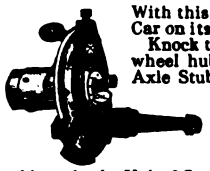
RIM-GRIP SUB-CASINGS reinforce the fabric of the tire at all points from bead to bead. They make a partially worn tire stronger than it ever was. It can be worn out completely and the sub-casing used in another tire. As the cost of equipping a car with new tires is much greater than last year, it will pay you to investigate Rim-Grip Sub-Casings. *Write for particulars.*

FISHER MANUFACTURING CO.

1706 PAYNE AVENUE, :: :: CLEVELAND, OHIO

This cut shows how sub-casing fits inside tire.

"Kant Slip"
Inner Liner
For Automobile Tires.



A complete inside fabric reinforcement. Enables you to get 500 to 1000 miles more from a nearly worn out tire. The flaps prevent slipping, therefore liner isn't stuck to tire and can be transferred from one to another and used over and over. Try the "Kant Slip" Inner Liner now, and get a few hundred miles more out of your old tires. It will pay.

Sold by dealers and by mail. Send for circular and prices.

All Sizes **FORD & LYON, Fitchburg, Mass.**

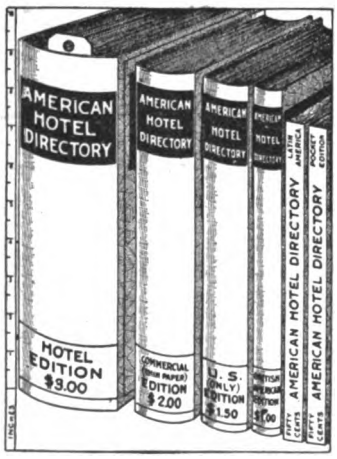
THE FIRST 2 BOOKS OF THEIR KIND IN THE WORLD

A Complete Automobile Business Education for $3.50

AUTOMOBILE BUSINESS
By J. H. NEWMARK

The first book in the world that discusses the automobile business from a money making standpoint. Every feature of it is thoroughly discussed from a dealer's view—opportunities that the industry presents today; best auto selling territories; organization; sales; advertising; promotion work; garage; service; accounting systems; and all other departments. 201 pages. Price $2.00 postpaid.



AUTOMOBILE SALESMANSHIP
By J. H. NEWMARK

A complete manual for the man desiring to sell automobiles; how a self propelled vehicle operates; simple definitions a salesman should know; manufacturing procedure in motor car factories—essentials of successful salesmanship; how to secure prospects; selling a car; steps necessary; what constitutes beauty, style, comfort, easy riding, convenience, power, flexibility; economy, durability, safety; how to interest prospects; demonstrations; securing order; women in the case; trading problem; electric vehicles; trucks; etc. 121 pages. Price $1.50 postpaid.

Address all orders for the above books to

THE MOTOR VEHICLE PUBLISHING CO.
71-73 Murray Street, New York.

THIS YEAR'S AMERICAN HOTEL DIRECTORY

YOU CANNOT ASK US A QUESTION ABOUT ANY CITY AND HOTEL OF THE WESTERN HEMISPHERE THAT WE CANNOT INSTANTLY ANSWER. WE WANT TO ASSIST YOU IN PLANNING YOUR ITINERARY OR ROUTING YOUR TRAVELING REPRESENTATIVES. LET ONE OF US BE YOUR PRIVATE BUREAU OF INFORMATION.

HOTEL EDITION, $3.00—That's the big brother, he knows as much as all the rest of the family put together. He is built for heavy work and rough usage at big hotels. He's informed on everything but the time table on North and South America, from Bermuda to Hawaii inclusive.

COMMERCIAL EDITION, $2.00—Knows just as much as his big brother, but not so strong, designed for smaller hotels and commercial offices, where he won't have to work so hard, still, with reasonable, careful use, he's long lived.

UNITED STATES EDITION, $1.50—A fine investment for any one who doesn't go outside of the United States, but when it is within these borders, you can't stump him with a reasonable question.

BRITISH AMERICAN EDITION, $1.00—This chap has completed a tour of all Canada, and the British American Islands, he knows all about these parts and the hotels.

LATIN-AMERICAN EDITION, 50c.—A little fellow to be sure, but still full of information about everywhere and everything fit for a white traveler to go or see in the Southland—from El Paso to Cape Horn.

POCKET EDITION, 50c.—The little book with the big circulation, designed for the traveler and his hand bag or coat pocket. Lists the principal cities, principal hotels, and points of interest in United States and Canada only.

All illustrated, printed on strong paper and cloth bound.

Either of the editions referred to above will be sent to any address on receipt of price. We would particularly recommend the **Pocket Edition at 50 cents**, as it will answer for the most part all practical purposes. Postage stamps accepted in payment. Address:

MOTOR VEHICLE PUBLISHING CO., 71-73 Murray Street, New York.

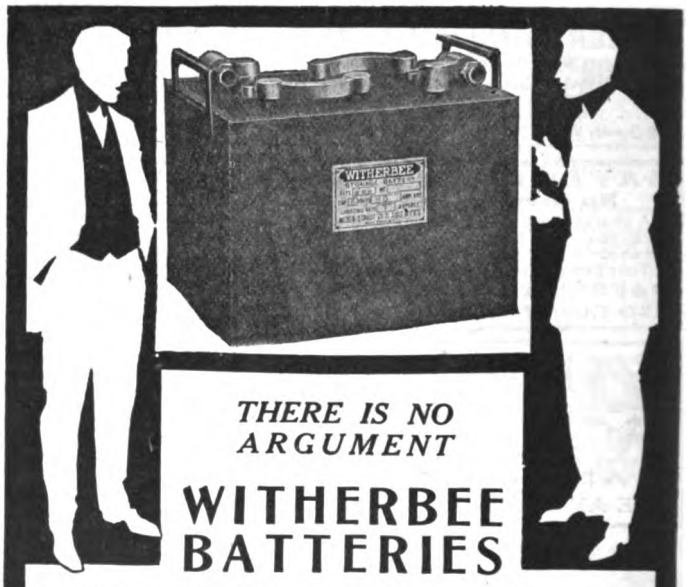
Add $250.00 A MONTH EXTRA To Your Business

REPAIR AUTOMOBILE TIRES

Sounds like a whole lot of money to clear extra every month. Seems almost impossible, but that is what hundreds of men are doing who have added a Tire Repair Department to their business. **The investment is small, the profit large and returns quick and all cash,** besides the demand for tire repairing and retreading is constantly growing. Your garage is by no means complete, your business is not as profitable as it can be until you get in on the Tire Repairing and Vulcanizing end.

THE HAYWOOD TIRE REPAIR EQUIPMENT



Answers all the requirements to successfully handle this end of the business. With it and a little business judgment, success is certain. Every year adds thousands of new auto owners. They are looking more and more to economical tire service. The day of discarded tires is over, the Haywood Equipment makes this possible.

HERE IS YOUR OPPORTUNITY

Either as a side line to your present automobile business or as a business by itself, the Haywood Equipment will make money for you. **Tires go wrong all the time.** You know that. Keep them in tune. Give your customers complete service—repair their tires and all. This builds business and makes you rich. Experience unnecessary. You can learn easy—or teach a boy to handle this end. Be the boss and make the money. Learn the details now. Investigate. Act quick. Be the first. Send name and address only. A postal will do.

HAYWOOD TIRE & EQUIPMENT CO.
965 Capitol Ave., Indianapolis, Ind.

THERE IS NO ARGUMENT

WITHERBEE BATTERIES

FROM the very start—years ago—we were determined to keep away from slip-shod methods—with the natural result that Witherbee Batteries are today famous all over the world—for longer service than others of the same rated capacity.

People **do** appreciate high quality—and they've beaten a path to our door. When we accept your money you can rest assured that you are getting the very highest quality battery known to man.

Every requirement in Lighting and Starting Batteries may be filled from our line.

Details of Dealer's proposition will be mailed—write to us this day. Are you a quality man? Desirable Territory still open.

WHO MAKES THE TIRE CASE

needed in every garage

ALLEN Draw-Off Panel

Sell your Gasolene or Oil thru the ALLEN System

protection for buyer and seller

You can sell gasolene by air pressure. The ALLEN System has the emphatic endorsement and approval of the National Fire Underwriters.

This System for storing and distributing gasolene, oil or any other volatile liquid is so constructed as to eliminate the possibility of ignition or explosion. Lowest possible fire insurance rates are assured.

The ALLEN System is in actual operation in many garages and mercantile establishments where it is giving perfect satisfaction.

The special ALLEN meter tells at a glance the amount of liquid drawn off. Speedily and easily operated.

The System is adapted to varying conditions of height without in any manner affecting the accuracy or safety.

A most practical installation from any up-to-date garage or service station.

FAIR LIST PRICES FAIR TREATMENT

The New Horseshoe Above the Door

GOODRICH TRADE MARK TIRES

Where You See This Sign Goodrich Tires are Stocked

BUT the Goodrich Dealer's Sign is the *sign* of the good *fortune* of *good business, not* of *luck.*

Unlike the old horseshoe, its good fortune is founded on *solid business sense*—Goodrich *marketing policies.*

It is a trade magnet because every tire user knows that where he sees that sign he takes no risk either with the dealer or the tire he buys.

He knows that Goodrich Fair Treatment stands behind the Goodrich Dealer's Sign ready to make good to him anything the tire may not.

This new "horseshoe" of good business is magnetized with pulling power of Goodrich's great *prestige* as the world's greatest and oldest rubber maker.

It is magnetized with the Goodrich *reputation,* which means quality of tires and good faith of guarantee, wherever rubber is known.

Sister sign of the Goodrich Guide Post which points the right way to a nation of automobilists, its friendly, familiar face welcomes every motoring tourist who passes your door.

Enlist all these forces and the great selling force of Goodrich's nation-wide advertising campaign—national monthlies and weeklies, the metropolitan dailies and your city press—

BY HAVING A GOODRICH DEALER'S SIGN OUTSIDE YOUR STORE SELLING FOR YOU.

GUARANTEE VISIBLE PUMPS CANNOT BE MANIPULATED

What Does This Mean to You?

Well, if you are a dealer, it means your use of Guarantee Visible Pumps establishes your reputation for fair dealing—giving your customers full measure always—and that record makes your garage headquarters for gasoline and oil sales.

If YOU are a car owner it means that when you buy from Guarantee Visible Pumps you ***see what you are getting and you get all you pay for.***

A Visible Measure

It eliminates all doubt, removes all suspicion of short measuring.

The fact that the car owner sees gasoline, or oil, draining from a glass measure right into his tank puts the touch of finality on the transaction. He goes away satisfied and he returns again, for he has become a steady customer.

Blind pumps do not encourage business.

The Guarantee Visible is a sure puller of trade.

Write us for particulars.

Here's the Opportunity

Are You the Man?

Here is an unusual business opportunity that will appeal to the ambitious, wide-awake business man because it contains actual proof of its value.

Our Proposition

Within the next thirty days, we will appoint about twenty men or firms in both Eastern and Western territory, to represent us as exclusive factory dealers in the sale and distribution of Gates Half-Sole Tires.

These appointments are worth from $500.00 to $1,500.00 per month to the men who are fortunate enough to get them, and for this reason, in the selection of these representatives we will consider only men who are energetic, wide-awake business-getters, with experience in handling men as well as in selling.

The Record of Our Other Dealers

About eight months ago, we ran an advertisement similar to this one. A large number of applications were received and from these we selected the men who were to be given the dealerships.

The exclusive selling rights that were given out at that time have become very valuable to those who hold them. Over thirty of these men have earned better than $1,000.00 per month in discounts and bonuses and have built up a well organized and permanently profitable business in their protected territories.

For over six months our entire output of seven hundred Half-Sole Tires per day has been taken by these established dealers, but within the next two weeks we will have our two new factory units, numbers 4 and 5, in operation and this will increase our daily production of Gates Half-Sole Tires from seven hundred to one thousand finished tires per day.

Here's your opportunity if you are the right man. What others are doing you can do.

What We Will Do For You

Every man who secures an exclusive dealership from us is immediately given the benefit of all inquiries and sales in his territory. An advertising campaign, using large size space in the local newspapers is carried on entirely at our expense. A Service Man and Tire Expert is sent out from the factory to assist in the installation of shop equipment and to properly instruct the dealer and his shop men in regard to the sale and application of the Half-Sole Tires. This service is rendered entirely at our expense and without any cost whatever to the dealer. We give it because our experience in the opening of new territory has taught us exactly what is necessary in order to insure the success of every man that we appoint.

What is Necessary to Qualify

Our first consideration is given to the type of man. He must be ambitious, wide-awake and capable of managing a business. A capital of only $250.00 to $1,500.00 (depending upon the size of the territory) is necessary at the beginning in order to carry a small stock of Gates Half-Sole Tires on hand ready for prompt delivery.

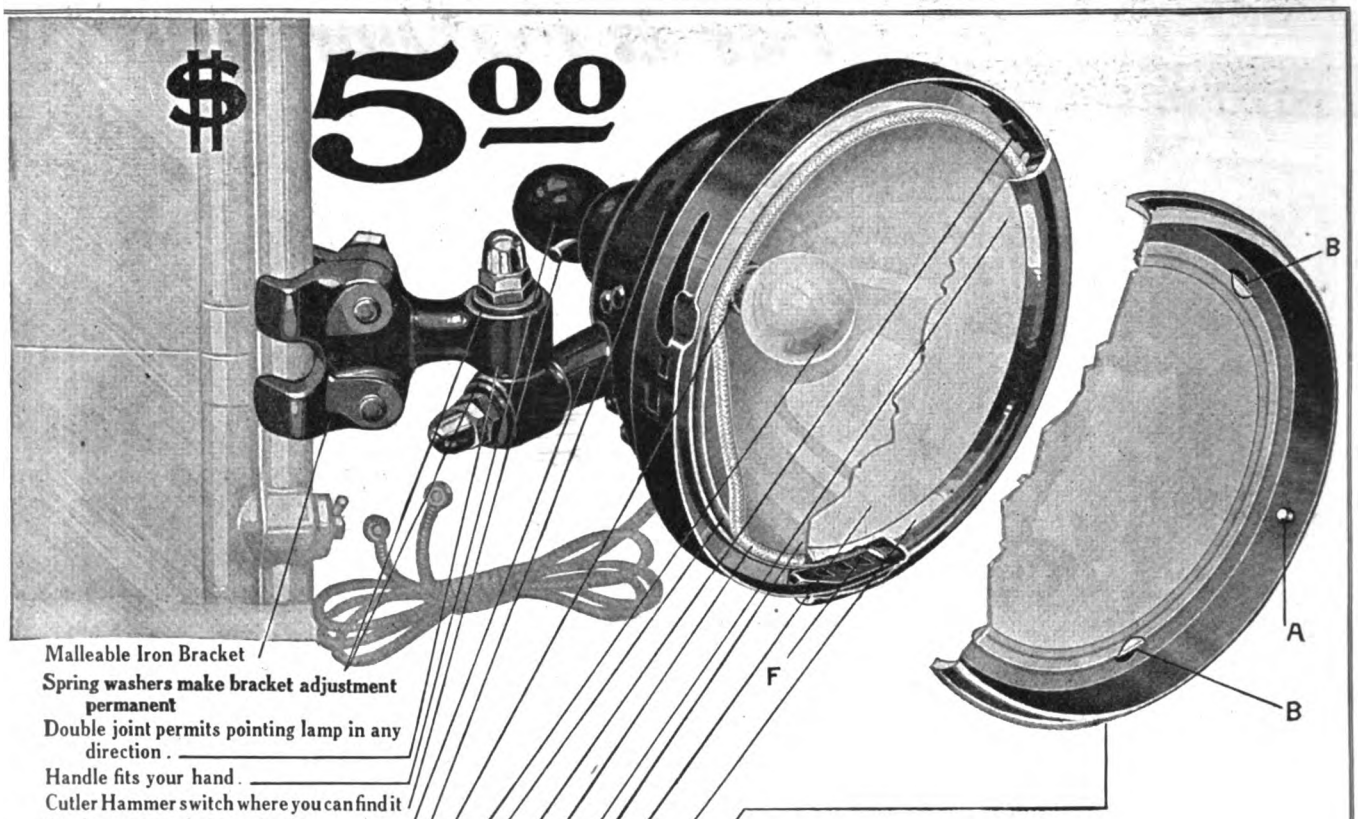
This is the kind of an opportunity that rarely presents itself—less than $500.00 in capital backed up by a live man with a desire to build and possess a business of his own will within a few months earn in discounts and bonuses each month more than the initial investment. Our proof of this statement is the fact that scores of other dealers are doing it.

Here is the Reason

Gates Half-Sole Tires sell for only one-half as much as the ordinary standard tires, still they are **guaranteed 3,500 miles without puncture** and this guarantee is backed with a million dollar capital. It is not strange after all that a hundred thousand motorists are using Gates Half-Soles and that more of them are going into service every day - just as fast as five hundred men working night and day in our three factories can turn them out.

Don't Delay—Act Promptly

A great many men will read this page. If you can qualify for one of these exclusive territories and are prepared to handle it, don't delay in writing us at once.



This is a Live Opportunity for the Right Man. Don't Pass It!

The International Rubber Company

98 West Tennessee Street **Denver, Colorado**

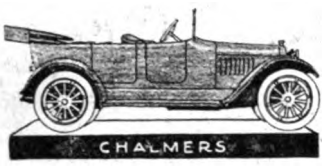
What Car Do You Drive?

IS its name among those mentioned here? If it is, the chances are ninety-nine out of a hundred that you feel the same as these owners do when you use Texaco Motor Oil.

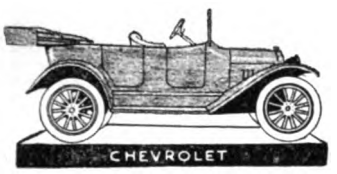
The expressions of opinion printed under the name of each car are quoted from unsolicited letters written about Texaco Motor Oil by different owners.*

So many thousands of motorists regularly use



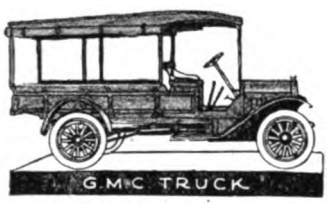
TEXACO MOTOR OIL

that those quoted are only a few from many hundreds which we have received. Innumerable drivers of Fords have written us. We have several letters from Pierce-Arrow owners, and so on.

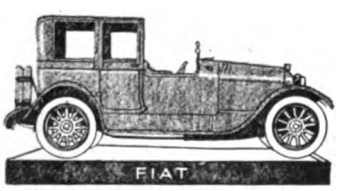


If the name of your car is not mentioned ask some friend, who drives the same make and uses Texaco, what results he gets. Perhaps you are a Texaco enthusiast yourself. If you are, we should be glad to hear from you and add the name of your car to our list. If you are not, it is easy to become one. Buy a one or five gallon can of Texaco Motor Oil and try it.

*Entire letter of any owner, with the name and address, will be sent you upon request.

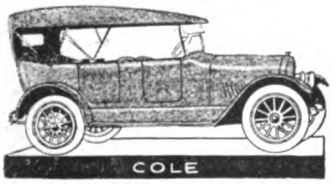


THE TEXAS COMPANY
New York Chicago Houston
Distributing Offices in Most Cities

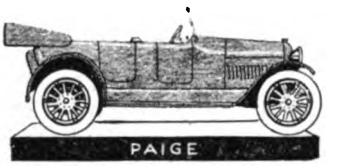


"I am glad to say that after a thorough test of your Texaco Motor Oil, it has proven to be exactly what you claim for it."

"My Chevrolet has been driven 8,500 miles. The valves have never been ground, and the motor has more power than when I bought it. I can truthfully say that there is none better than Texaco."

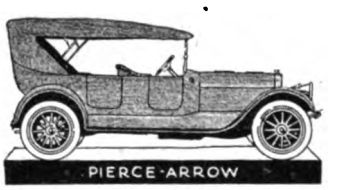


"We have a G. M. C. Truck in which we have used your lubricating oil for two years with very good results, finding it a good lubricant and free from carbon."

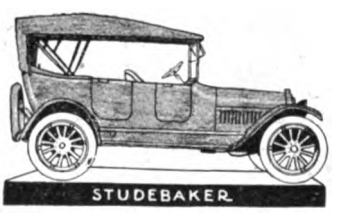


"I can with every confidence recommend Texaco Motor Oil to all motorists. Both from an economical and efficient point of view. I have used nothing that has given me such good results."

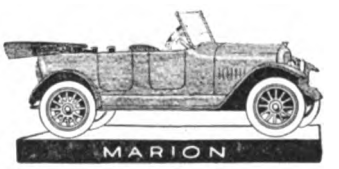
"I have run my Ford car on Texaco Motor Oil 7,500 miles without cleaning my spark plugs and get very best of compression today."



"It gives me better satisfaction than any other I have ever used."

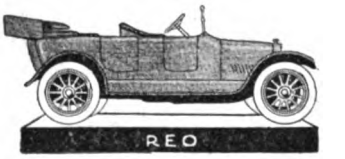


"Your oil has given the best of satisfaction on Paige cars, in fact I have had no troubles myself nor have had any but favorable reports from my sub-agents and customers."



"I have no carbon troubles whatever and both the oil and gasoline are entirely satisfactory. In fact, I think that your motor oil is the best that I have ever tried for an Overland car."

"My car is a Pierce-Arrow, seven passenger, and it runs better today than it has since I have had it, due no doubt, to the use of Texaco Motor Oil."

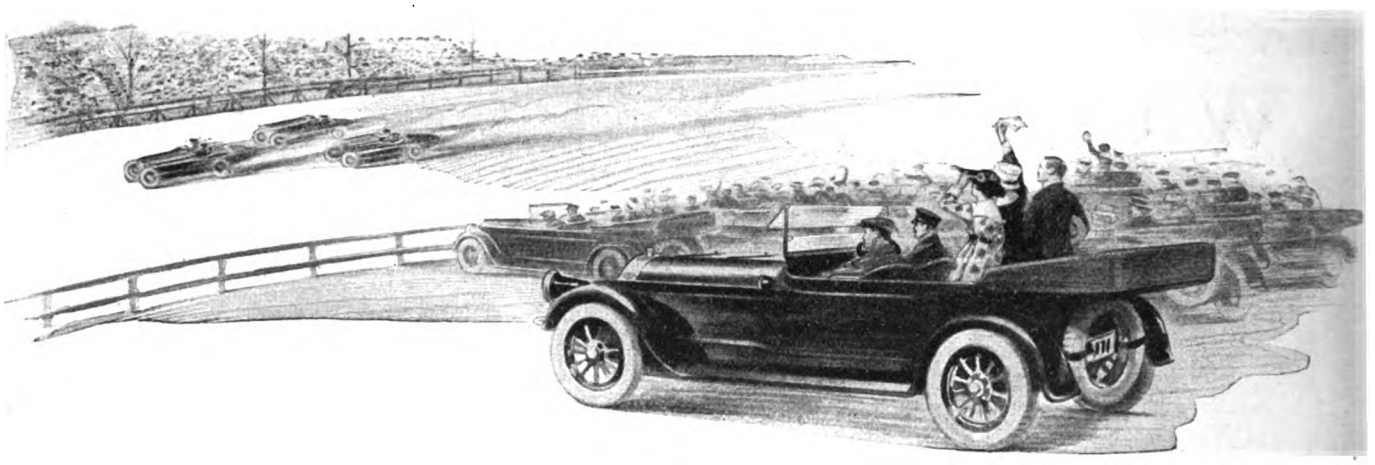


"We expect to get over 12,000 miles out of 15 gallons of your oil. Can't ask for better service than your oil gives."

"It gives perfect lubrication, with a minimum amount of carbon in the cylinders, in fact there is hardly any carbon noticeable."

"It has given perfect satisfaction in every respect."

"On five gallons of this oil the car made a few miles in excess of 5,200, and during this time I have had absolutely no lubrication troubles of any character."



"It increases my power and speed and decreases my fuel consumption greatly. It has reduced my running expenses fully 15%."

"I would say that it is the best I have used yet."

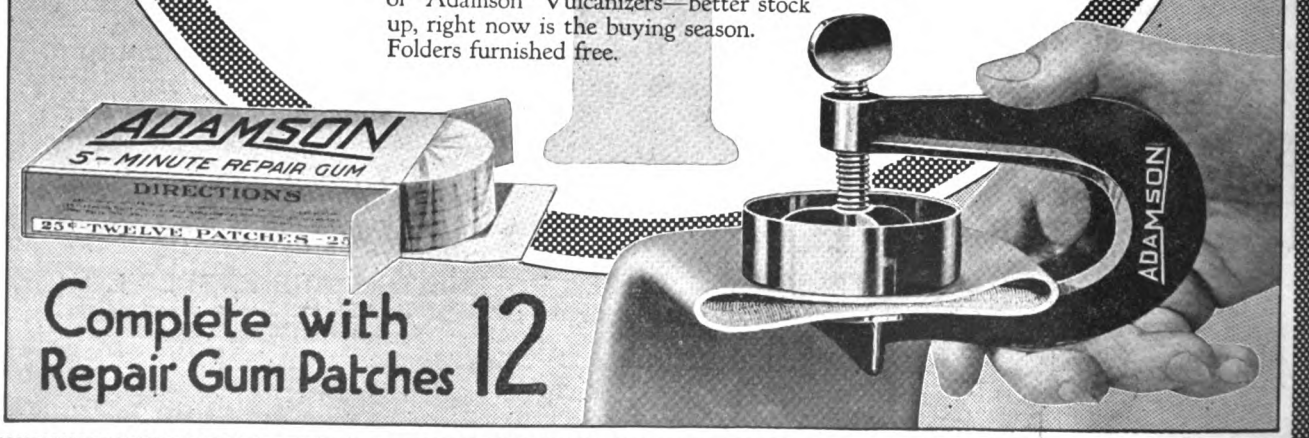
THE NEW ADAMSON MODEL "E"

5-MINUTE VULCANIZER

Five minutes with the "Adamson" Model E, the tube is repaired to *stay repaired* and—you are on your way again.

Anywhere, you can mend a puncture without fuss, muss or delay. Gasoline—always handy—is used to provide heat. And an "Adamson" patch is as strong as the rest of the tube—it defies frictional heat, however fast you drive.

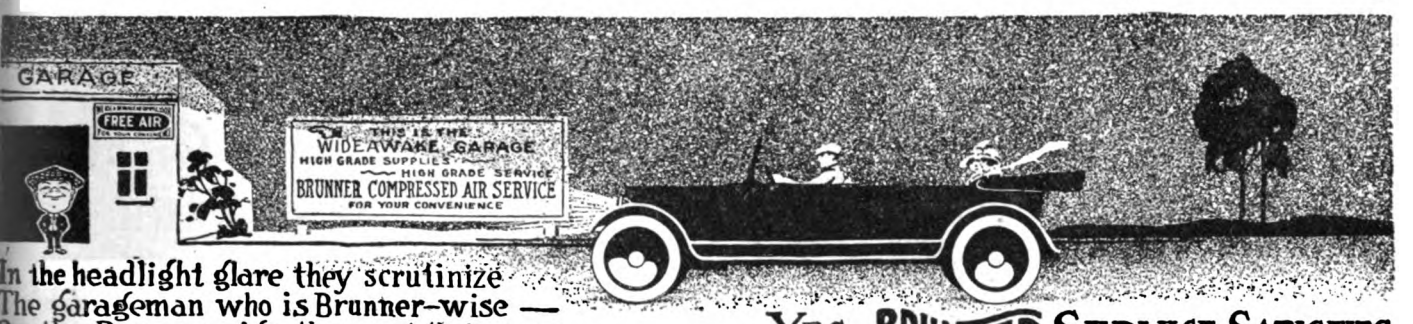


The price is inconsiderable—just a dollar for the complete outfit, including a box of a dozen "Adamson" 5-Minute repair gum patches. Extra box of 12 patches, 25c.

Next time you're in your dealer's store ask him for an "Adamson"—he sells lots of them.

ADAMSON MANUFACTURING CO.,
EAST PALESTINE, OHIO.

Complete Line of various sizes of "Adamson" Vulcanizing Outfits for tube and tire repairing; prices range from $1.00 to $12.00.



Wise Dealers realize the enormous popularity of "Adamson" Vulcanizers—better stock up, right now is the buying season. Folders furnished free.

Complete with 12 Repair Gum Patches

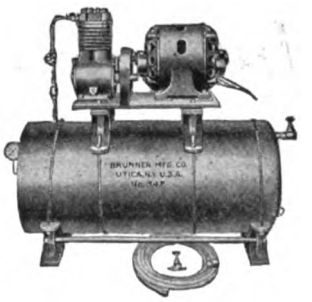
BRUNNER

In the headlight glare they scrutinize
The garageman who is Brunner-wise —
On the Brunner sign they rest their eyes
And stop for air and – some supplies.

YES, BRUNNER SERVICE SATISFIES



SERVICE that satisfies is the one big dominant factor in the administration of the garage business of today, and the success of the modern garage is dependent entirely upon the class of service it renders.

Mr. Garageman, when they flash their headlights on you at night, are you prepared to render such service? Does your service satisfy? If not, then you should seriously consider the matter of installing Brunner Service, because Brunner Service always satisfies.

INCREASE YOUR INCOME BY IMPROVING YOUR SERVICE

INSTALL A BRUNNER AIR COMPRESSOR

No matter how good your compressed air service may be, Mr. Garageman, Brunner Service would be an improvement, because it would strengthen your standing with the trade you have and—it would bring to your door the trade of the Brunnerwise Motorist and increase your sales of gasoline and supplies, because the Brunnerwise Motorist is a liberal spender and appreciates the service that satisfies.

The Brunner is the pioneer of the present day air compressors—it was not put on the market ten years before the garage was thought of—it was designed and built especially for the garageman's use and it has been consistently demonstrating its sterling qualities to the garageman in the garage ever since we have had garages.

The sale of the Brunner Air Compressor to the garageman is far greater than any other air compressor made—the reason is obvious.

YOU CAN BANK ON A BRUNNER AIR COMPRESSOR

And any one of the high-class reputable jobbing houses who distribute the Brunner Line will be glad to recommend and guarantee a Brunner outfit to meet your special requirements. We will be glad to send you the name of the Brunner Jobber covering your town, and our engineers will be very glad to assist you in making your compressed air service—a service that satisfies.

Our No. 14 Catalog and Garageman's Handbook on Compressed Air are yours for the asking. Write for these books today and get the facts regarding the Garage Air Compressor situation.

Ford Owners and Dealers Prove A. B. C. Starter

BEST "FIND" OF THE YEAR

Hand-cranking is dirty, laborious, and out of date.

Up-to-date Ford dealers have found the way to increase dealer profits and user satisfaction—by urging Ford owners to install the efficient A. B. C. two-unit Starting and Lighting System.

This remarkable system puts Ford starting in the same class with the highest priced cars.

A·B·C

TWO-UNIT SIX-VOLT

STARTING & LIGHTING SYSTEM

for Ford Cars

Last January it made its first appearance in a national way. Today it dominates the field. Thousands are in use in all parts of the world.

The A. B. C. Starter conforms more closely to Ford engineering and construction than any starting and lighting device ever invented. Its overwhelming structural advantages are conceded by Ford dealers and owners.

Its weight is distributed, by units, on both sides of the engine. No drag or strain from starting or generating.

Noiseless and powerful in operation. Its effective generator-drive employs a fibre, leather and metal link belt moving in a V-type pulley. This gives the highest possible degree of pulling contact.

The A. B. C. operates under all weather conditions, at the pressing of the button. Guaranteed to be efficient and mechanically correct. Easiest to install, ruggedly built, and longest-lived.

Many letters from grateful Ford owners bear witness to the supreme service-value of the A. B. C.

Ford dealers who have not taken on this most essential of all Ford accessories should find out at once all about the A. B. C. For your convenience, a coupon is attached. Fill out and mail it today, and learn our generous and stimulating 1917-18 dealer proposition.

Dealers never drop the A. B. C.

PHONES 2015 AND 2016

Norton Taxicab Company

"WE GO ANYWHERE"

OFFICE AND GARAGE 220 W. SIXTH ST.

Joplin, Mo., June 18th, 1917.

McQuay-Norris Manufacturing Co.,
612 Bryant Bldg.,
Kansas City, Mo.

Gentlemen:

In reply to your inquiry relative to the results we are obtaining from your McQuay-Norris Leak-Proof Piston Rings which we have installed in our taxicab fleet, wish to state that we keep a record of the cost to operate our cars and find we are getting more mileage on gasoline and oil, and a great deal more power than we used to get before using your rings - and we have very little trouble from carbon deposits on the pistons and spark plugs.

We certainly consider your rings a good investment as they pay for themselves in a short time and save money for us.

Yours very truly,
NORTON TAXICAB COMPANY.

A Man Is Judged By The Customers He Keeps

And whether you keep your customers or whether you see them going across the street to trade, after buying from you a few times, depends entirely upon how much SATISFACTION you wrap up with every item purchased at your store, and you know it, too.

THE HALLADAY LINE

The Halladay line of Bumpers and other Automobile Necessities is the line which gives COMPLETE SATISFACTION, both to the customer in performance and to the dealer in profits.

It is the Nationally Advertised line that keeps your customers crossing your threshold, smiling, and keeps the cash register ringing and you smiling.

PART OF THE HALLADAY LINE

Halladay Bumpers include Front and Rear type to fit all cars of Standard design and several cars of specialized design, such as Buick, Cadillac, Cole, Chevrolet, Franklin, Ford, Mitchell, Overland, Packard, Pathfinder, Briscoe, Dodge and others.

Halladay Flexlevers were the first and remain the foremost of the lever type of shock absorbers. They are made in two styles: heavy type for all cars with full or three-quarter elliptic springs and a Ford type for all Ford Cars.

Halladay Double Arm Shock Absorbers are the cheapest, really efficient shock absorbers for Ford Cars on the market.

Halladay Tilting Steering Wheel is an instantaneous acting, self-locking, tilting steering wheel for Ford Cars. It is applied in place of the steering wheel without any alteration of any other part of the steering gear.

Halladay Can Tipper is the greatest convenience ever offered for Public or Private garage. It carries standard, square or round, five-gallon cans in such manner that oil can be drawn from the cans with one hand, allowing the other hand free to hold the receptacle in which the oil is being poured.

The Halladay Line includes many other conveniences and necessities such as Running Board Luggage Carriers, Side and Rear Tire Holders, Valve Lifters, Jacks, Oil Can Holders, etc.

Live Hardware Dealers who wish to know more about the Halladay Line of Satisfaction and Profit Producers may have our catalog and full particulars. Just address us as shown below.

No Back Pressure With the Petry

PATENTED

SIZES, 1½" to 3"
PRICES, $3.50 to $5.00

Inside dimensions of the cut-out at every point are larger than this inside dimension of the exhaust pipe, and no air pockets can be formed that might cause back pressure.

The Petry Cut-Out is quickly and easily installed, having seven points of adjustment—and once applied, its position is permanent.

Gas-tight joints. Adjustable spring well away from all heat. No fluttering of valve. No strain on exhaust pipe. Gases are discharged through a flaring opening which intensifies sound, facilitating tuning up of motor.

Easy to install and operate—no complicated parts to get out of order. A size perfectly suited to every car.

Multiply—

the cylinders in a motor and you multiply the need of a spark plug **with ability to withstand the rigorous punishment delivered by a multi-cylindered motor—**

MASTER Calorite Spark Plugs

have been designed to meet the heavy demands of present day gasoline engines—**Neither extremes of heat or cold, nor trip hammer blows of high compression, high speed motors—can worry them—**

Their scientific design—

The superior materials entering into their construction provide a factor of resistance to trouble practically double that of ordinary plugs—

True, Master Spark Plugs command a reasonable price but they prove that quality is economy—In their long lived, dependable service—

There is a Master Calorite Spark Plug for every variety of motor,

And the retail price is amply justified by their efficiency and durability.

$1.00 and $1.25 Retail—Depending Upon the Size

Let us send you full details regarding our proposition to the trade. You will find it most attractive.

The Jumbo Economizer

THE ONLY GAS SAVER ON THE MARKET THAT IS ABSOLUTELY GUARANTEED TO SAVE 20% GASOLINE

The Jumbo Economizer is an auxiliary Air Valve which is to be attached to the manifold of any gasoline engine for the purpose of increasing the speed of the engine by introducing air into the manifold after the engine is started, and in this manner accelerate the engine without the additional use of gasoline. This principle is well-known and the fact that the Economizer has been on the market since 1912 is sufficient proof that the Economizer is a success from every standpoint.

HOLDFORD BRAKES

SAFETY FIRST

PRACTICAL

POSITIVE

ASSURES YOUR SAFETY

HOLDFORD BRAKES are high-grade external contracting brakes for Ford cars which can be easily and quickly installed to act from the hand lever as emergency brakes, or from the foot pedal as service brakes. Designed in accordance with the best engineering practice; the band and brace are of steel, the toggle crank and bracket are dropped forgings and the lining J-M non-burn. Do not drag when released, no readjustment for wear is necessary and oiling is easy.

HOLDFORD BRAKES save wear and tear and will be attached by the wise owner on his pleasure car, delivery car or truck. They will positively stop a Ford with locked wheels on *any grade, at any speed, with any load.* Not necessary to remove old brakes.

When Ordering State Whether for Hand or Foot.

Try at Our Expense this wonderful Repair Outfit

Weight 90 lbs. boxed

Stewart Handy Worker "SIX-IN-ONE"

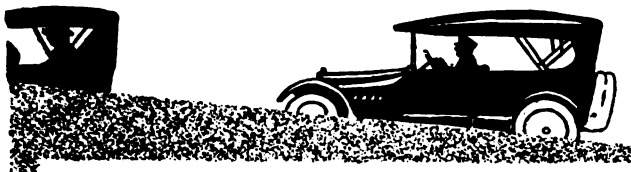
Price Complete $14

Handiest combination of tools you ever saw. Just the thing for the garage, public or private. Wonderful value for the money. If you were to buy separately all of the tools you get with this outfit, and get tools of the same high quality, strength and durability, THEY WOULD COST YOU AT LEAST $25.

A COMPLETE, COMPACT WORK-SHOP

A strong, practical anvil; powerful vise up to 4½ inches, width of jaw 4 inches; a sure-grip steel pipe vise, takes up to 1½ in. pipe; A Corundum grinding wheel 5 inches by 1 inch; a two-speed drill press with 2 drills; a metal cutting wedge and driving mechanism of three speeds—direct, 4 to 1 and 16 to 1—easily regulated by changing handle grip. It operates grinding wheel, buffing wheel, and many other similar tools.

With the STEWART HANDY WORKER you can do car repairing, blacksmith work, home repairing, make plumbing repairs, keep knives and other tools sharp and in good working condition.



OUR SPECIAL TRIAL OFFER

Send for one of these great combination outfits today. Order with this understanding: If you aren't thoroughly satisfied in every way, you can ship it back and we will return every cent you paid out. THOUSANDS HAVE BEEN SENT OUT ON THIS BASIS AND NOT ONE HAS BEEN RETURNED.

Send only $2 with your order, and pay the balance when it arrives. BOOKLET GLADLY MAILED ON REQUEST. But the best way to appreciate this wonderful outfit is to order it, on our special trial offer.

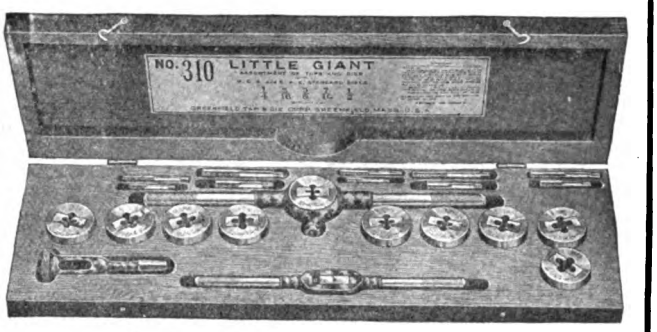
Guaranteed for 10,000 Miles

EVERY Brictson Tire is sold under a specific 10,000 mile written service guarantee. This guarantee is the longest and strongest ever put behind a pneumatic tire and is a positive protection to every purchaser.

"Absolutely Puncture Proof"

Brictson Tires are puncture proof, and proof against blowouts, skidding, rut wear, rim cuts, and can't be damaged by oil or gasoline. Wonderful resiliency, easy riding and economy commend them to every car owner.

The Big One-fourth Retread Feature



Should the tread surface wear out after 10,000 miles of service you can get a new retread for one-fourth the original cost of the tire, instead of buying a new tire and you keep the remaining three-fourths in your pocket. With ordinary service the Brictson Tire should run enough beyond the 10,000 miles to require one or two extra retreads. The more retreads you use the cheaper your service.

FREE TRIAL OFFER

To convince you the Brictson Tire will give satisfaction TRY THEM ON YOUR CAR AT OUR EXPENSE. Write today for this Free Trial Offer, a copy of our guarantee and full information about Brictson Tires.

"KEEP THE CAR ON THE GO"

"NORMA"

"NORMA" BALL BEARINGS

(Patented)

The failure of a magneto bearing will stop a car or truck as completely as a broken axle. The failure of a bearing in the lighting generator is as serious as a break-down of the whole electrical system. No bearing in a car or truck is more important than the magneto and generator bearings.

As to the superlative dependability of "NORMA" Ball Bearings, makers of high-grade magnetos and lighting generators are practically unanimous—expressing their confidence by standardizing their apparatus on "NORMA" Ball Bearings.

ALL YOUR GAIN

It Is a Hobby with Some Men to See How Good They Can Make a Thing

IN THIS CASE IT HAPPENS TO BE THE

TESTITE PISTON RING

And a very—VERY Good Ring It Is

Made with an eye single to absolute technical precision. You would hardly imagine it possible that such a supposedly common thing as a piston ring could be made so uncommonly good.

Testite Piston Rings are made in all sizes to fit all motors.

Testite Piston Rings save gas by utilizing the entire fuel charge in the production of power. There is no waste. No loss of power, no waste of exploded gases past piston ring openings.

Testite Piston Rings are a boon to marine, and also to aeroplane motors, where the highest compression is so vitally important.

Testite Piston Rings make your motor measure more power, make it more responsive, and though the highest in efficiency, are the lowest in price for piston rings of their character.

Every ring is inclosed in a separate envelope with directions for installation and are packed twelve in a box for the trade.

Our literature, we believe, treats the Piston Ring question in an intelligent manner—learn more—write us—today—that's better than forgetting it.

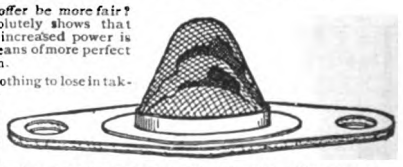
GASCO

GASOLENE ECONOMIZER



NOW—IT'S UP TO YOU!

Truth is never crushed to earth if given a square deal. Pin a dollar bill to your letterhead—mail it to us and prove Gasco's distinguishing traits.

First, determine the speed of your motor while idling and with the throttle all the way down.

Then unbolt the carburetor flange from the intake manifold and insert the Gasco as if it were a gasket, tighten up the bolts and start up the motor.

If the motor doesn't run faster than it did before, just send the Gasco back and we'll refund your money.

Can any offer be more fair? This test absolutely shows that with a Gasco increased power is obtained by means of more perfect fuel combustion.

You have nothing to lose in taking advantage of this offer, and you can readily prove for yourself that Gasco will save its cost in a short time in the saving of fuel, besides adding power, reducing carbon, and preventing fire due to backfire.

Thousands sold—one large concern purchased 3200.

Dealers everywhere find it a quick seller and a good profit-producer. Our sales plan calls for a small investment and gives a quick turnover. Write today for particulars.

Motorists Make their own Tire Repairs!

Thousands of motorists who thought they could never repair a tire are now using the Shaler Vul-Kit. They find it easy to mend tubes and casings with this wonderful vulcanizer. They carry it right with them in their tool box and they're always ready for any blow-out or puncture, no matter how far out in the country it happens. With a Shaler Vul-Kit, you can seal the small cuts in time—before sand, dirt and moisture have been pounded into them to rot the fabric and ruin the tire.

SHALER

Vul-Kit For Tubes and Casings **$3.50**

Simple to use. Automatic heat control. No need to watch or regulate it. No chance to overcure or undercure the tire. No exposed blaze or liquid fuel to spill. Seals the cut in the tire with new rubber, protecting the fabric and making the damaged part like new.

Dealers—Write! Besides the Vul-Kit shown here there are other models of Shaler Vulcanizers for Motorists and Garages from $1.50 up, as well as complete plants for public repair shops. Write on your letterhead for our new catalog.

BAILEY BALL THRUST

Replaces Thrust Washers at Left (Gear) side of

FORD and CHEVROLET 490 DIFFERENTIAL

Here is the real answer to that far reaching cry for an efficient remedy of axle difficulties, noisy or broken gears—the answer to that need for a bearing that will replace the old style, inefficient thrust washers used as standard equipment in Ford and Chevrolet 490 differentials, that through their sliding contact wear thin in no time, and cause drive gears to shift away from the drive pinion, creating havoc with the gears.

THIS NEWEST INVENTION

Of a master engineer, the BAILEY BALL THRUST BEARING, is an exact replacement made to fit to the thousandth part of an inch, and will positively keep gears in proper mesh, make them run quietly and last indefinitely. They will not wear thin.

DEALERS GARAGEMEN REPAIRMEN

All over the United States and Canada, wise men are stocking this bearing. Go after this replacement business. It is a source of profit for you and yours providing you can supply the customer's needs at a moment's notice. It will not do to order at the last minute, because the car-owner insists upon immediate service, and you must be prepared.

LIST PRICE, $3.75

Here's The Trade-Mark That Buyers Of Automobile Springs Are Learning To Look For

Harvey RACINE

The Harvey trade-mark is our guarantee of quality and means extreme limit in auto spring service. It protects the dealer and repairman, too, for it means that we, the manufacturers, must maintain the high standard we have established for Harvey Springs. These good springs are a live, money-making proposition for any dealer or repairman who wants to increase his spring replacement business—and profits. If you don't know our jobber in your territory, write for his name at once.

Harvey RACINE Springs Do Not Break

They are made of the finest selected steel, have no weak spots and are guaranteed from end to end. If a spring proves defective at any point we will replace it. Harvey springs are made in sizes for practically every make and model of car. Each spring is an exact duplicate of the spring it is intended to replace and fits with an accuracy that will surprise you.

You owe it to your customers—to your own best business judgment to sell springs of recognized merit. Harvey springs meet every demand for wear and service and give absolute satisfaction to the car owner.

FREE

Every Dealer, Garageman and Repairman should write for the Harvey Auto Spring Book No. 4, just off the press, which contains a complete list of springs for all the leading makes and models of cars. Gives sizes, weights, measurements, prices, and other valuable information about automobile springs that has never been published before. It is a quick and ready reference book and an invaluable aid in ordering replacements. We mail it free.

Conserve America's Dwindling Supply, for Its Most Valuable Uses

THE world faces a leather famine. Tremendous demand and decreasing supply have caused an alarming scarcity. Sole leather has already sold for over a dollar a pound. Shoes have advanced from 50 per cent to 100 per cent, and shoe manufacturers predict that, without quick relief, leather shoes of good grade will sell for $15 to $20 a pair.

The largest leather consuming industry is the shoe business. Automobile upholstery ranks next. Every automobile upholstered in leather takes leather enough to make 3 dozen pairs of shoes. Hence:

Motor car buyers must soon decide which they will do without—leather in shoes or leather in automobiles.

Du Pont Fabrikoid Motor Quality offers the best solution to the problem. More cars are now upholstered in it than any other material.

Those automobile makers still using split leather acknowledge to us that it is inferior to Motor Quality Fabrikoid, but they hesitate to adopt the latter for fear some buyers may still think split (commonly sold as "genuine leather") is better. When buying an automobile tell the dealer you prefer one upholstered in Du Pont Fabrikoid Motor Quality. You will get a more serviceable—more lasting and more superior upholstery than split leather and you will do your share in the conservation of leather.

Many cars are already upholstered in Du Pont Motor Quality Fabrikoid. You can get it on *any* car if you will ask for it.

Write for names of makers using it.

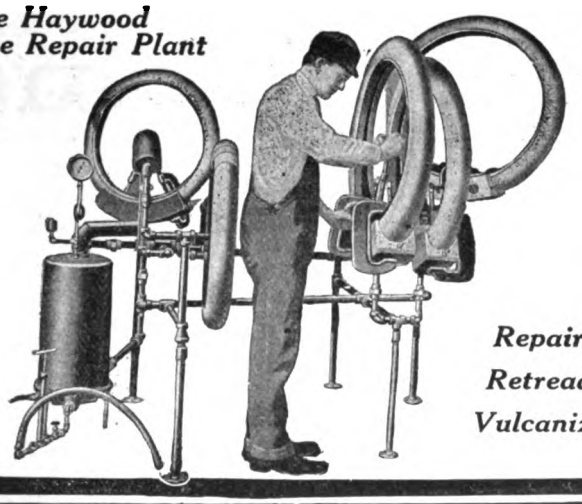
FRICTION is the BUSY BEE that takes the HONEY out of MOTORING

It takes the sweetness out of the running qualities of your car. It removes the joy—and makes your car too intimate with the repair shop. Kill Friction. Do it effectively and efficiently with

NON-FLUID OIL

It will keep your car a better car for a longer time. Non-Fluid Oil in the transmission, differential and bearings will check the wear and tear of Friction; will quiet gears, cushion metal-to-metal contacts and make your car the sweetest running thing on wheels.



Non-Fluid Oil is three times as long-lasting and durable as any grease at any price. It is the most efficient lubricant in grease form. But it is not a common grease. It is infinitely better, because it starts checking friction the minute it is applied. Non-Fluid Oil does not melt under high temperatures, cannot thin out or leak from bearings or gears.

Ask your dealer for Non-Fluid Oil. Sold only in orange colored cans. Send today for sample and literature.

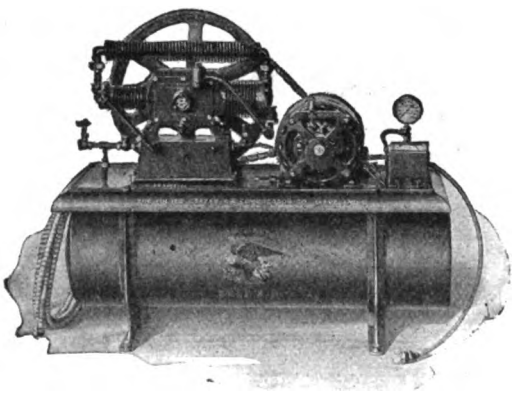
TWO-STAGE AIR U.S. AIR COMPRESSORS

All Autoists Endorse the Two-Stage Idea



SUPPOSE, next time you saw an autoist inflating a tire with a hand pump you were to enquire why he didn't used a single cylinder (single-stage) pump.

He'd probably reply, with no small amount of sarcasm, that: "he wasn't doing it for exercise and he didn't have all day for the operation either."

Of course, you wouldn't think of asking such a question in view of existing circumstances. You know, and everyone knows, that the compound or two-stage hand pump has completely annihilated the single-cylinder single-stage pump, simply because it was superior beyond comparison.

The first compound hand pump was designed to utilize a principle already existing in two-stage power driven compressors, and the success of the compound pump in millions of instances proves the correctness and superiority of this principle beyond question. In other words, autoists using two-stage pumps and abandoning others endorse the two-stage idea as distinctly superior.

United States **two-stage** compressors are made in a range of sizes and combinations to meet every requirement. To buy them means to obtain the fullest possible measure of satisfaction. Send for Catalog today.

The New Sectional Overlap Lazyback Cover

An Exclusive Feature in

GORDON Seat Covers
TAILORED TO FIT

That Revolutionizes the Sale and Application of Seat Covers

Patent Applied For

This new sectional overlap feature provides four advantages not heretofore offered in any make of Seat Covers:

Easy Application of Covers Makes Misfits Impossible No Strain on Fabric or Buttons Easy Riding Qualities

They are the missing features which have stood between the car owners' demand for Seat Covers and the Dealer's success in meeting it.

The sectional construction of the new "Gordon" Seat Covers makes their application merely a job of following illustrated instructions sent with each set. You can't misplace a part and cannot fail to secure a perfect, smoothly fitting Seat Cover.

Put on one section at a time. Each section bears a ticket telling where it goes.

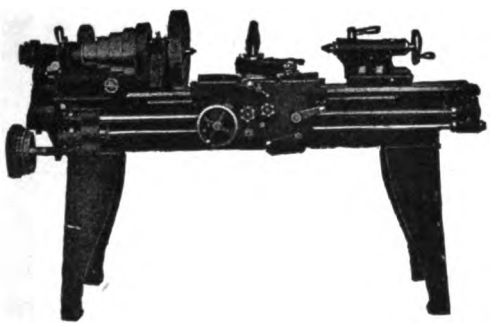
The overlap provides for the variation in the upholstery of Cars of the same model.

When you lean back, the overlap gives with the lazyback and there is no strain on the fabric or fastenings.

This new style "Gordon" Cover is not more difficult to put on than spare Tire Covers. One man can handle the job alone. You can now sell "Gordon" Seat Covers "put on" and make a good, clean profit on every sale. They remove all the troubles that have taught you to fight shy of Seat Covers—they put within your reach a market that promises more than anything else in the accessory field.

"Gordon" Seat Covers are made for more than one thousand American made automobiles—from twenty-four beautiful, strongly woven fabrics in sun-fast shades of brown, tan and gray.

We make shipment of your orders in three days, tell you how to put them on and furnish fasteners in the same color as the Cover fabric.



Investigate this new style "Gordon" Cover at once. It means real money to every accessory dealer.

Norwesco Soldering Paste

A scientific compound that causes the solder to flow on and fuse nicely and is much easier to handle thanacid. Retail Price, 25c

Norwesco Rim and Gasket Shellac is a much needed article in the repair shop. It is used for perfecting gasket joints and for cementing bicycle tires to their rims. 2½ oz. Swab Bottles 15c. Larger containers from 25c to $3.00.

Brass-Kote is a quick drying enamel that transforms the brass part of a car to a gloss black or hard rubber finish. Requires no filler. Dries quickly and does not chip nor crack.

Pint Cans 60c, Half Pint 35c

Norwesco Valve Grinding Compound. This valve grinding compound grinds a valve down quickly to a smooth, uniform seat, contains no ground glass nor powdered emery. This double-end box contains two ounces of fine and two ounces of coarse.

Retail Price 25c

Norwesco Graphite Coating

Is a perfect rust resistant for auto rims and springs. It also serves as a lubricant between rim and tire. Dries in three minutes and can be applied while changing tires.

Half Pint Cans 40c

Profitable to Dealers because Popular with Motorists

That's the simple secret of the growing demand for

"Chemically Correct" Automobile Specialties

Every "Chemically Correct" article offers the motorist a short cut in car upkeep enabling him to get more efficiency as well as more pleasure out of his car.

Write for complete catalog or consult your jobber at once.

Norwesco Neatsfoot Compound restores clutch and brake facings giving them their original grip, whether they be leather, cork or composition.

Pint Cans, 30c

Carbonox. The "Chemically Correct" carbon remover. Loosens the carbon and it is blown out the exhaust. Used twice a month it keeps the engine free from carbon all the time.

Pint Cans, 50c

Never-Burn is a baking enamel for automobile engines. The heat bakes it on and it adheres like part of the metal itself. Two finishes: Gloss Black and Battleship Gray.

Pint Cans 60c
Half Pint 35c

Skalex is the "Chemically Correct" radiator cleaner. It is a dry powder that dissolves in the hot water of the radiator and removes all rust scale and sediment. Does not attack the metal. Retail Price, 50c

Norwesco special Mohair Top Dressing both dyes and waterproofs mohair with one operation. A quart can does a touring car top; a pint is sufficient for a runabout top.

Quart Cans 90c
Pint Cans 50c

SE-MENT-OL

The Original Self-Acting Radiator Cement

It is popular with motorists everywhere because we advertise it nationally and because it

"Finds the Leak and Fixes It"

In ten minutes it repairs one or more radiator leaks. The motorist then drains and refills his radiator and it is just like new.

LOCATING THE GARAGE.

How Westerners Solve Problem of Housing the Motor Car on the Premises.

BY FELIX J. KOCH.

The housing of the automobile is a problem that should be solved by those contemplating the building of a home, and the garage should be considered even

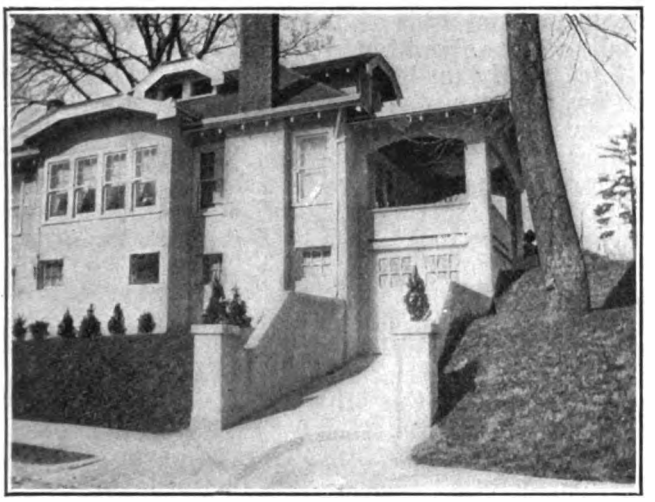

Fig. 1.—An attractive type of attached garage which is convenient and heated by house system.

if one is only slightly interested in the motor car. It does not require other than a little thought to decide where the garage should be located, and having arrived at a decision it is easy to determine what type you would build if you decide to invest in the automobile.

Personal taste determines largely whether you would have this connected squarely with your own residence,—off a ways,—or else sufficiently distant from your own home to comprise almost a distinct edifice and provide a home for the chauffeur and his family. Presented herewith are some interesting examples of garages in the big American Middle West and taken in the environs of Cincinnati.

The illustration shown at Fig 1 is of an attractive type of attached garage, that is to say, it is built under the veranda of the owner's dwelling. This admits of its being heated in the colder months by the same system which heats the owner's home and makes it warm and convenient for working in without extra cost at all seasons.

Where no chauffeur is maintained, this garage seems to possess every advantage. Properly cemented and with due provision against fire, it avoids the possibility of unpleasant odors reaching the house proper. The design is said not to increase the house insurance rates. With a driveway cut to it through the lawn, and this neatly edged, as shown, one may drive in, after the theater,—lock the door and leave the machine after simply extinguishing the lights. It is but a step for the owner up the stairs on his way to bed.

Some folks, however, do not care for this type, particularly if several members of the family use the same car. However careful one may be with the machine he is almost certain to wake the sleeping members of the family on his return, if it be kept in what is substantially the cellar.

The picture shows the home of a western newspaperman who in coming home through the dark streets has found it of decided advantage to use his own machine and garage it at home. His home, however, is built on an attractive knoll, the top of which is about on a level with the garage roof, —and in this way the family is spared the noise made when an automobile is run squarely into practically one's cellar.

More pleasant still for all concerned, and for those who can afford chauffeurs, is the structure shown at Fig. 2.

In addition to an attractive residence of concrete there is built at one side of the garden and so well to the rear that no sound or odors can reach the dwelling, a two-story garage. The ground floor front is used for automobiles. At the rear is the wash-room and supply-room.

Stairs lead to the upper floor, a cozy apartment or flat being provided for the chauffeur, although only unmarried men are employed at this place. The arrangement is convenient for both the owner and driver.

The detached garage possesses numerous advantages and particularly appeals to the man who

Fig. 2.—A detached type of garage which combines dwelling for the chauffeur at the rear.

builds a small home such as a bungalow. With the attached type of garage the residence is subordinated to a certain extent; that is, when the residence is very small the garage detracts from it.

AMONG THE PENNSYLVANIA MOUNTAINS.

Interesting Points for the Garage Man and Car Owner.

BY JAMES F. HOBART, M. E.

A Good Old Ford.

"Yes, I've been up here in this crack in the mountains, on the headwaters of the Schuylkill River for more than seven weeks and I have seen some things in automobiling which were not to be found along the gravel stretches in Indiana."

Just a few Pennsylvania Dutch around here. At least "four out of every three" confess by their speech to such parentage. One of them, working as a laborer at 22½ cents per hour, has a considerable farm, carried on by his women and children. He comes to work each morning in a fine buggy, drawn

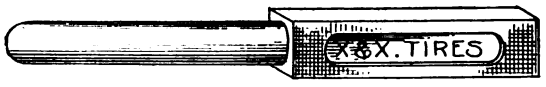

Fig. 1.—Stock Tire Tool.

by a good horse, and in the evening, you may see him and his entire family speeding to town in a good touring car—his own property, and paid for too.

Stopping for weeks at a Road House, miles from a village or town, has its drawbacks, of course, but many things are to be seen there, of interest to automobile drivers, and I like to spend all spare moments talking with the car drivers who stop to change tires, pump in a bit of air and incidentally to "unload schooners on the bar."

Just now, a contractor from a neighboring village stopped to change an inner tube. He came from town with a tire not pumped up quite as it should have been and struck two miles of state road which had recently been treated with a spreading along its center of broken stone. Part of the road was covered with stone about three-quarters of an inch across each broken side, while other stretches of the road had been covered with stones much larger, many of them one and one-half inches across. And the state, in mending this road, instead of covering the broken stone, or at least rolling it down, leaves the freshly broken stone just as it was spread from the teams and the automobiles which pay a heavy license each year, have to roll down the sharp stones with their expensive rubber tires. And it is an expensive way—for the tire owners.

A little Ford car pays $10 a year for the privilege of rolling down crushed rock on state roads. That is "going some" even for mountain travel! The contractor above mentioned had a little Ford of 1910 make which was still doing full duty, being driven almost continually and carrying five or six men to work in the morning and bringing them back at night. Between whiles, the little car was used as a motor truck and carried lumber and material over the mountains, where it is "up hill both ways."

The car had been so arranged that a truck platform seven feet long could in three minutes' time be slipped over the frame back of the seat and the contractor stated that he often carried half a ton on the little truck platform, besides three or four men upon the seats. He also stated, in reply to my questions, that the car was owned and operated by himself and his two brothers, all contractors; that the car cost him $125 in 1910, and that some one of the three had been driving it almost continually since that date.

They had kept careful account, he said, and figured that the cost of running the machine since they owned it, was just about 1¼ cents per passenger mile.

"All winter," he said, "we have been building some houses five miles across the mountains. Each day, we take five men, sometimes six, up there in the morning and bring them home at night. The cost for the round trip, about 10 miles for 5 men, is 31¼ cents against a 14 cent fare on the railroad, or 70 cents per day for the five round trips." He said, "The railroad hasn't anything here on my little old Ford."

In getting ready to change the inner tube, the gentleman brought out, with the jack, two little tools, one a stock affair about as shown by Fig. 1. The other was a tool which he said was a great saver of time. This tool is shown by Fig. 2 and was evidently home made from a bit of old wagon spring.

Each tool was about ten inches long. The stock tool, Fig. 1, evidently made of cast or malleable iron and given away as a tire advertisement. But the "XX" tire exists only in the imagination of the writer, therefore, don't try to find that make of tire in order to get one of these tools, which, the contractor said was good when starting to take off a tire, but after once started, the tool shown by Fig. 2 had the other one "skinned a mile!"

The tool shown by Fig. 2, as stated, made from a bit of wagon spring, was about 1¼" wide, worked down quite thin at either end and both ends were bent in opposite directions, one end being bent to a longer radius than the other end. With this tool, after the tire had been started with the stock tool, it could very quickly be freed from the rim of the wheel and before I had fairly examined the home made tool, the contractor had placed another inner tube inside the rim and was putting it back again upon the wheel.

An Advertising Scheme.

One "Pennsylvania Dutchman" who evidently had been crossed with Yankee stock, worked a bit of clever advertising whenever he had a few minutes in town. He had a printer strike off several thousand neat little cards of attractive design, the cards giving

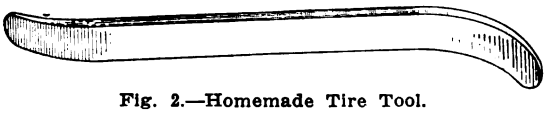

Fig. 2.—Homemade Tire Tool.

the advertiser's name and address and a comprehensive list of the things which could be done at the repair shop in question. The card ended with the legend:

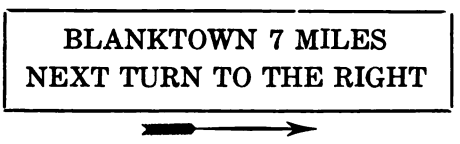
"Good work, Quick work and Honest Prices."

Whenever the advertiser found cars parked, he would place one of his cards conspicuously upon one of the seats of the car and go on his way rejoicing. The scheme was a clever one and should bring in a good deal of work for "trial trips" at least. Further patronage, would of course depend upon the manner in which the first job was handled and charged for. However, the scheme has the earmarks of success. Should the garage man have no time to distribute the cards, a boy or a girl could do the work as well and a good deal cheaper than he could do it himself.

In view of the tremendous number of parked auto-

Digitized by Google

mobiles to be found at nearly all times in towns and cities, it seems that some enterprising individual might carry the matter a bit farther and print a folder, souvenir style, containing useful local information, together with the publicity notes of several standard automobile accessories and requirements and have the pamphlets distributed regularly to parked automobiles inside the district which would naturally benefit the several advertisers.



Marking Inner Tubes for Patches.

One day, while watching a garage man test out an inner tube for leakage, I saw him use a neat little kink for locating and sizing the patch to be applied. When the tube came from the water trough, the surface of the rubber was of course, very wet and the bubbling of the air through the leaks could be very plainly seen.

As fast as the leaks were found, while the tube was still wet, the garage man marked on the rubber with an aniline pencil, the size and shape of the patch to be applied. Then, taking care not to handle the marked places, as soon as the water dried off there were several patch sizes and locations, from which shapes the patches were quickly cut with the shears. The aniline markings also served as very convenient guides for applying the cement, also for placing the patches upon the tube.

A Road Sign Kink.

While motoring along near Lancaster, Pa., recently, a very comprehensive road sign came into view, bearing information of just the right kind. The sign, a wooden board of the usual construction, was lettered as follows, the words being painted in letters at least four inches high and so plain that there was no need of reading the words for they simply THREW themselves at the passerby. The sign read:

That "Turn to the Right" was what did the business. It helped a whole lot and perhaps prevented the driver of the car from becoming crosseyed through watching both sides of the road at the same time.

Testing Inner Tubes.

A tank about thirty inches long, eight inches wide and ten inches deep, partially filled with water, forms the tube testing apparatus of some repair shops. The better tanks are built of galvanized steel. Cheaper ones are made of wood. In some shops, half of an oil barrel does tank duty for testing tubes and in more than one instance, the writer has seen the test tank "hived" in a dark corner where it is almost impossible to see well enough to detect small leaks.

One of the best tube tanks the writer has seen was made of plate glass, bottom, sides and ends, all bolted and cemented together in regular aquarium fashion. This tank was not hidden in a dark corner. It was placed where there was a good light, and to make things still easier, two powerful incandescent lights were located upon "lazy-tongs" fixtures in such a manner that the lights could be placed almost anywhere either underneath or around the tank during a tube test.

As the light could shine through the walls or the bottom of the water tank it was easy to detect leaks, even while the tube was under water, for it was not necessary to remove the tube from the tank in order to see whether or not air was escaping through the walls of the tube.

But, certain conditions must be met in order to detect leaks. It is sometimes necessary to do more than barely fill a tube with air and place it in the tank, in order to find the leak. The writer recently saw a man spend more than an hour looking for a leak in a tube, but, try as he might, he could not locate it. Still, he knew that a leak existed because the tire "went down" slowly, as often as it was pumped up, thereby showing that the leak was a small one.

The owner, after trying in vain to locate the leak, and having failed even when the tube was lathered by means of a brush, with soapy water, the garage man took a hand in the game. He tried the tube in the tank just once but did not waste five minutes in searching for the leak, then he pumped more air into the tube and a second immersion in the tank showed just where the trouble was.

"It's this way," said the garage man. "When you put just a little air into a tube, the strength of the rubber may be sufficient to close the hole so tightly that no air can get through it. But when you put on a bit more pressure, the force of the air overcomes that of the rubber and you can find the leak at once. You must be careful, however, not to pump in too much air or the the tube may be stretched and weakened. Usually a pound or two pressure is enough to show almost any leaks. There is another thing. You see that I barely submerge that portion of the tube where I am looking for a leak. If the tube be immersed too deeply, the static pressure of the water will tend to keep the air from leaking out for the water is trying just as hard to get into the tube as the air is trying to get out. If you immerse a tube 26 inches deep, the static pressure of the water will be about one pound per square inch, and that will help much to keep the air from coming out. However, we never immerse tubes that deep, but I always take care to do the testing with the tube barely immersed."

Tightening Nuts with a Brace-Wrench.

It goes without saying, that a socket wrench either fitted into a bit-brace or else with a handle made like a brace, is a very good tool with which to remove and replace wheel bolts. But it should also go without saying—which it doesn't always—that a good many men don't use the brace wrench right. When a nut is caught in the brace wrench, the nut should be screwed home without once removing the wrench from the nut.

But there are occasionally times when it is pretty hard work to do thus and even experienced workmen prefer to remove the brace-wrench when the nut is nearly home and replace the wrench again and again in order to obtain a more favorable leverage.

It is well and proper to use the brace-wrench thus, but it is not good workmanship to remove and replace a brace-wrench each time a sixth or a quarter turn is given to the nut. But recently the writer watched a man put on all the bolts which hold the wheel together and he made a removal and a replacement of the wrench for each of the six sides of the "hex" nuts, at each and every turn.

It seemed very unmechanical to the writer, the

Digitized by Google

wasting of time in that manner, but there were compensating points to be considered, especially from the view point of the garage man, who, when the writer remarked to him the waste of time by the automobile owner, said:

"Now don't you say a word to that man. Just let him go his way and take his time. While he is monkeying with that wheel, he is not burning up gasoline or wearing out tires. But he is paying for my time and for that of my man who is waiting on the nut-screwing business, therefore, don't you say a word to him about the matter."

Perhaps that point is worth considering from the garage man's standpoint, but I noticed that his men never took short strokes with the brace-wrench. Instead of that, the brace went right around and around until the nuts were screwed home. When the nut got nearly home and went hard, the workman would obtain the leverage necessary to give the required turn by shifting the position of his elbow. The elbow of the arm which did the turning act would be moved in one direction or another until the forearm was perpendicular to the portions of the brace which acted as crank arms. With the arm and elbow in this position, a considerable leverage could be exerted to revolve the brace, something which could not be done when the forearm and the brace were all in the same line. Just bear this matter in mind next time you have trouble in sufficiently tightening a hard going nut with a brace-wrench.

Reversed Throttle and Gas Connections.

I saw a queer happening recently. A car was put together and the engine started for a test when, to the surprise and disgust of the man at the wheel, the spark, the gas and the throttle were found badly mixed up. When, after starting the engine, the levers were moved to advance the spark and to cut down the gas, just the reverse happened and the engine "died" two or three times before it was found that the lever connections on the wheel were badly reversed.

Upon looking for the cause of the troubles, it was discovered that the several connections to the levers were by means of small cranks with connecting links, and, when the cranks and links were connected together in a certain way, the opening and closing movements of the several levers on the wheel were exactly reversed, thus causing the confusion and the "killing" of the engine as above described.

While all automobiles cannot be mis-connected in the manner noted above, still it is a very good plan, when connecting up levers and links of any description, to see for sure, whether or not the movement of the hand lever is in the right direction after connections have been made.

PLAN FUEL ECONOMY CAMPAIGN.

Automobile Organizations Urge Conservation of Supply to Aid Nation.

A nation-wide campaign is under way to conserve the fuel supply so that there will be ample gasoline for the legitimate requirements of owners and the army and the navy. The National Automobile Chamber of Commerce, Society of Automotive Engineers, Motor and Accessory Manufacturers and the American Automobile Association are co-operating in the movement.

It is estimated that the United States army will require 350,000,000 gallons of gasoline for airplanes, trucks, tractors, automobiles, etc. This does not mean that owners need lay up their cars, but should use them either for trade or pleasure purposes thoughtfully and judiciously. If this be done there will be no shortage of fuel in this country.

Those familiar with the fuel situation do not believe there is any reason for anticipating drastic action by the government or the suspension of the customary useful operation of pleasure cars, but these experts do point out that it is the patriotic and unselfish duty of motorists to be economical with fuel. It is not a question of saving money or saving fuel to prevent its price being raised, but of conserving the supply of fuel itself so that there will be ample for war needs.

The situation in this country cannot be compared with that of England, because England is entirely dependent upon imports for her fuel supply, whereas this country is a large producer and exports huge quantities of gasoline and oil. During the fiscal year ending June 30, 1917, the United States exported 425,703,130 gallons of gasoline and naphtha as compared with 294,779,809 gallons in the previous fiscal year. Exports of crude, illuminating, lubricating and other mineral oils increased from 2,148,668,174 gallons in the twelve months ending June 30, 1916, to 2,323,735,304 gallons during the last fiscal year.

Of the 2,500,000,000 gallons of fuel obtained in this country last year about one-half was utilized by motor vehicles in this country. If only a 10 per cent. saving is effected by the conservation or economical plan by motorists it will save 125,000,000 gallons of fuel in the next twelve months. This economy is possible and without involving any great hardship to the motorist; in fact, the suggestions made for effecting the economy will be a benefit aside from the actual cost thereof. The plan involves the economical operation of motor cars by adjusting the carburetor to the leanest possible mixture and the placing of the machine in the best possible operating condition.

This campaign of economy is to be conducted through dealers, distributors, manufacturers, garagemen and repairmen. It is the intention of those having direction of the campaign to issue to the 27,000 dealers, 24,000 garages and 13,000 repairmen a placard to be hung on the walls of the service station, garage, repair shop, etc., urging users of fuel to economize, and among the means available are the following:

Do not use gasoline for washing or cleaning. Use kerosene for removing grease and other foreign elements from articles to be cleaned.

Do not spill gasoline or allow it to drip when filling a tank, etc. This is wasteful and dangerous.

Do not expose gasoline to the air as it evaporates rapidly and gives off a vapor that is easily ignited.

Do not run your engines when the car is standing. Cars are fitted with motor starters. Use them, as it is good for the battery under normal conditions.

Adjust carburetors to the leanest possible mixture. A lean mixture tends to prevent the formation of carbon.

Properly fitting piston rings means good compression. A poor compression means loss of power.

Form the habit of shutting off the fuel supply at the tank or feed supply pipe. It will avoid the possibility of loss of fuel should the carburetor flood.

Digitized by Google

Keep all bearings well lubricated, for friction is the foe of fuel economy.

In cold weather keep the radiator and hood covered when leaving the car exposed. It is a good plan to cover part of the radiator even when driving on cold days.

Keep tires inflated to the pressure recommended by the maker. Soft tires take considerably more power than those properly inflated.

Do not drive at top speed. The fuel consumption increases with speed. Ascertain the speed at which the car operates most economically.

Change gears, drop into the second rather than attempt to climb a hill with a wide open throttle. It will save both fuel and the car.

Do not use cars needlessly or aimlessly. By exercise of forethought a number of errands can be combined, so that one trip to town or elsewhere will serve as well as two.

Reduce the amount of riding for mere pleasure by shortening such trips or cutting down their frequency.

Effort is to be made to extend the campaign of economy to all users of gasoline, and in many instances it is possible to filter the used fluid and use it over again. There is a possibility that many of the whiskey distillers will produce alcohol in the near future and this fuel mixed with gasoline is being used successfully by the French government.

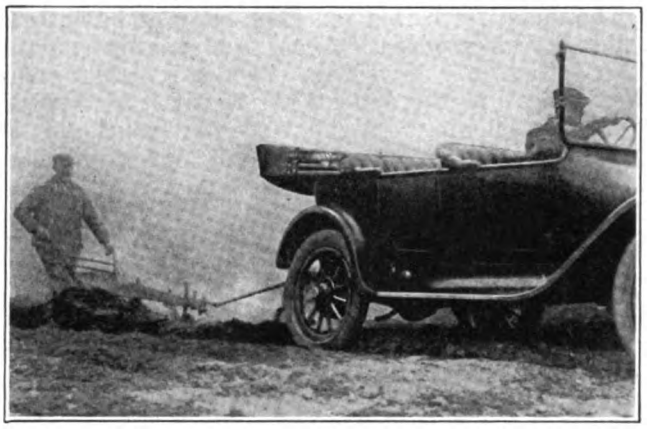
New oil fields, new refining processes and the campaign of economy are expected to and will help the fuel situation to the benefit of the government and all other users.

Frothing in a Battery During Charging.

Gasing, or boiling of the electrode of a battery, takes place near, and on the completion of, a charge. When a 2-volt cell is charged, its electromotive force rises rapidly from 1.8 to a little over 2.2 volts, and then slowly to 2.3, at which point the charge is almost complete. After attaining this pressure a rapid rise takes place to about 2.6 volts, during which period gas is freely evolved, the electrolyte having the appearance of boiling. If the electrolyte be at all dirty the rapid gas production will result in frothing to a certain extent, and it would be advisable to subject the acid solution to a close scrutiny.

Too high a charging current, or, what amounts to the same thing, too rapid a charging rate, results in exceedingly rapid decomposition of the electrolyte and violet gasing. The area of the plates is too small for the current to act upon, and in consequence the energy is wasted in decomposing the solution. The rapid gas production tends to drive the active material off the plates, especially if the positives be at all fragile or unhealthy. The displaced active material forms a mud or sediment in the cells, and may, when gasing is taking place, result in discoloration of the bubbles.

The charging rate for best results should be about one-tenth of the capacity of the cell in ampere hours. Thus a 40 ampere hour cell requires a charging current of 4 amperes, etc.



Care should be taken to ensure that only pure distilled water is used for refilling purposes, and if acid be spilt the liquid must be made up again to the correct strength.

Actual frothing, apart from gasing, is to be traced to the use of wooden separators between the plates. Such separators undergo a special treatment to rid them of injurious wood acids, and it may be that during this treatment products are formed which lead to frothing on charge, especially if a cell be new.

If the vent plugs are in good order and allow of free ventilation without spilling taking place, no harm will result, even if the cell does froth, as very careful analysis has failed to reveal any detrimental results. Inferior celluloid cases, under certain conditions, give rise to the production of nitric acid, and this may have a disintegrating action upon the plates.

How He Plows.

A. H. Long, a gardener of Belmont, Mass., solved the plowing problem without much worry. He hitched his plow to his Dodge Brothers motor car. With a friend at the wheel and the car going six miles an hour Mr. Long turned over approximately 2½ acres a day. A double gang plow used in the same manner would turn five times as much soil a

Latest method of plowing.

day as is possible with a single plow and team. In many cities, amateur gardeners are being charged high prices for plowing, owing to the excessive demand, but Mr. Long's suggestion offers a ready remedy. A speed of twelve miles an hour was maintained for some time during the experiment but the possibility of danger, due to the presence of stones, was responsible for Mr. Long's opinion that half as fast was fast enough.

New Dyke's Encyclopedia.

The sixth edition, the 1918 model, so to speak, of Dyke's Automobile and Gasoline Engine Encyclopedia is out. The series published under this head in the past have always been noticeable for the practical manner in which the principle, construction, operation, maintenance and repair of motor cars have been treated, but the new edition is even more so. The work of revision has been most complete and a large number of new subjects with illustrations have been added. One of the features of the book is the simple manner of discussing the subjects. It will appeal to the novice as well as the experienced motorist and will be found to be a valuable book of reference for the repairman and garageman, containing as it does the latest developments in motor vehicle construction. The index is well arranged and the desired information is readily obtainable.

SPARK GAPS.

Varied Steps in Their Development and How They Have Been Improved.

From a paper delivered in Chicago at the National Gas Engine Convention by Morris R. Machol.—The history of the spark gap goes away back to about 1900. Racing drivers discovered that when spark plugs went bad by forming an auxiliary gap outside of spark plugs could make these spark plugs work. The method was to tie a piece of wood to the spark plug, tie the wire to the wood and thus form a gap. The spark plug worked all right, but the spark in the open air brought with it many disadvantages. There was the very great loss of electricity which was discharged into the air; the high resistance of the air, resulting in a very heavy amperage drawn from the system, and the result was that the batteries ran down quickly and coils were very frequently punctured, due to high amperage, and because of the increased resistance of the air gap, also a higher voltage. Spark gaps of this nature appeared on the market even within recent years.

The usual form is a red fiber body and two brass points for electrodes. Of course high amperage and high voltage not only drain the battery and damage the coil, coil points and magneto, but it also results in finally burning off the electrode points of the spark gap, so that the device soon burns itself into an inefficient condition. It was, however, continually open to the objection that it was not fireproof and that the exposed spark was liable to cause damage from fire.

The next step in the process was the development of a glass enclosed device. The glass cylinder was made, to the end of which was attached metal caps, carrying the electrode points. This device still has the disadvantage of discharging all of the current across the air gap with consequent high resistance, high amperage and heat, and although this design would seem to make the device fireproof it had the disadvantage of confining the air around the points —the result being that the discharge soon ionized or nitrogenized the air inside the device, which practically short-circuited the device itself, and excepting when starting the motor, it very materially reduced the efficiency of the device. The effect was that ionizing the atmosphere inside the device still further increased the heat with the result that the points burned off very rapidly, and the glass cracked and broke.

The next improvement was to introduce a dielectric block which would mechanically hold the two caps together. The effect of this was that when the heat broke the glass the device did not fall apart. The next improvement was to use mica instead of glass, and this did overcome the disadvantage of breaking the glass, which did not, however, make the device entirely fireproof, and neither did it overcome the effects of excessive amperage, excessive heat and necessity for readjusting or renewing the spark-gap electrode points.

There were some spark gaps introduced in the market in which the entire gap was surrounded by a cylinder of metal. This device is fireproof, but it does not give the advantage of a visible spark, and it does not prevent the electrode points from corroding or burning off, due to the high amperage or intense heat, resulting from discharging all of the current across the air gap. The ionizing of the atmosphere inside of this device also materially assists the corrosion of the electrode points.

The only practical spark gap is one that will be fireproof and ventilated, and one in which there is no possible chance for the electrode points to corrode. Such a device must first have a distance or center block of fiber or bakelite or some other substance of extremely high dielectric resistance. This center block holds firmly in place the terminals which contain the spark-gap electrode point. Through holes drilled in the center block the spark becomes visible. The device has two caps, one at each end, which are made of fiber and impregnated with carbon so that they become electrical conductors. Between the caps, and surrounding the center block, is a screen which has the official mesh of the Davy miner lamp. This screen is made of copper, oxidized black so that the spark across the gap is easily visible. The Davy gauze makes the device absolutely fireproof even against as inflammable a substance as marsh gas. The device now becomes a true electrical condenser. One type of condenser consists of parallel strata of tinfoil, separated by layers of mica, where the conductor is the tinfoil and the dielectric is the mica. In the device I have described the copper gauze is the conductor, conducting the electricity in parallel lines, and the air contained inside the gauze is the dielectric, so that the device becomes a true electrical conductor, increasing the voltage and decreasing the amperage. Practically, in this device, only a portion of the electricity jumps the air gap, which, of course, keeps the amperage very low. The device is amply ventilated through the Davy gauze, which prevents even a low amperage from developing any heat at the electrode points.

The electrode points in this device are made of platinum substitute, as platinum is too expensive and difficult to get. The platinum substitute is composed largely of nickel and will do absolutely the same work. This spark gap has a peculiar effect on electric current. In the case of battery and coil, the direct current from the battery becomes a pulsating current, when it leaves the coil.

In the case of a magneto we get straight alternating current electricity—in either event, the current in jumping the gap changes its nature, becomes an oscillating current of very high frequency and takes on some of the properties of static electricity, in that it will seek its opposite pole. The result is that even when a spark plug is short-circuited with carbon, graphite or oil, this current will ignore the short and jump the gap at the spark plug points. The use of this spark device, therefore, first absolutely insures against possibility of spark plug trouble. Furthermore, the spark plug cannot fail to fire. Broken porcelain, carbon, oil and even water will not prevent the plug from firing. The next advantage is the visibility of the spark. The device becomes practically a window into the cylinder. If the gaps show a spark and there is any trouble, it stands to reason that it must be carburetor trouble. If but one gap fails to show a spark, then the trouble must lie in the distributor, and following that particular lead to the distributor will locate the trouble at once. If the motor will not start and none of the gaps show a spark, the trouble must be with the

Digitized by Google

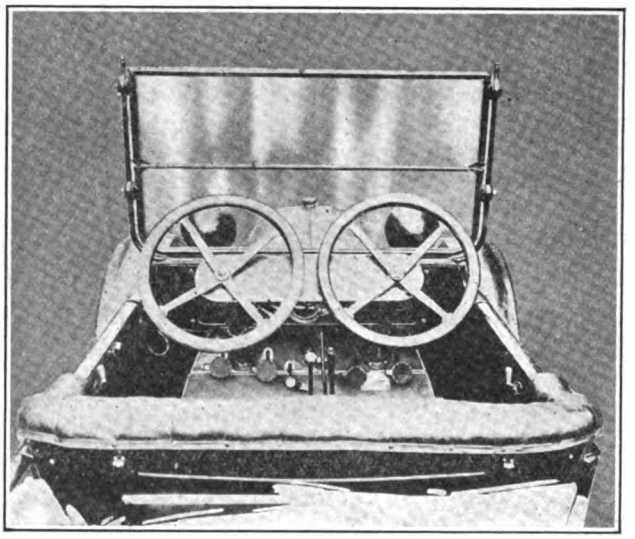
magneto. The visible spark is a wonderful aid in timing a motor. A finger held over the pet-cock will indicate when that cylinder has compression, and the spark gap will then tell which terminal is giving a spark at that time, whereupon it becomes a simple matter to connect up that particular terminal with the cylinder compression.

The spark that is produced at the point of the spark plug when the spark gap is in series with the spark plug is a fatter, stronger, better spark than would otherwise be produced. This gives a little more power and quicker ignition. It is self-evident that the better spark makes easier starting. You have all had the experience of putting a new magneto on a car and having to cut down the adjustment of the carburetor, because with the better spark it was not necessary to have so rich a mixture. The spark produced with the spark gap permits of the use of a leaner mixture, which not only saves gasoline, but also cuts down carbon deposits in the cylinder. This is because carbon comes largely from the partially burned gasoline, resulting from the use of too rich a mixture. Oxygen has a greater affinity for hydrogen than for carbon, and with too rich a mixture the hydrogen is burned out, leaving the carbon.

Another advantage is that with the spark gap all plugs give the same intense, high-frequency spark, no matter whether they are old or new, good or bad, dirty or clean, broken or whole. The result is an even torque motor, which means less vibration, less pounding of the bearings and less wear and tear.

The fact that the device described is a condenser means that, although the voltage is increased, amperage is reduced, consequently with the lower amperage the spark plug electrode points will not burn out. The lower amperage lengthens the life of the battery. Even in the case of a short-circuited plug where the electrode points are in actual metallic contact, the spark gap becomes a safety gap and prevents the possibility of drawing all the amperage that the system will produce across the magneto or coil points, and thus burning out these expensive platinum points.

Auto Thieves Have New Scheme.



That the automobile thief is ingenious and can be classed as brainy is revealed by a new scheme uncovered by the police of New York City. It appears that the police officer is no longer safe to ask a suspect about to drive off with a car if the machine is being stolen, for the person may be the owner and again he may not. The policeman cannot very well dispute the evidence offered as to ownership, which is an owner's card, license, etc. It appears that the new method of stealing a car is one that is likely to give the authorities some trouble, for according to the Police Bulletin, the first step taken by the average automobile thief is to ascertain the make, type and horsepower of the car he intends stealing. With this information at hand he goes to the office of the Secretary of State, gives details of the car he has in view, pays the specified fee and receives the usual license plates, the owner's card certifying that his car has been duly registered being mailed to the address given."

Then the gentleman in question, having obeyed the law so far, goes out and steals the car. If the car is stopped by an officer a few minutes later he is in at least the position of being able to make the suspicious cop stop and scratch his head meditatively while looking over the "proofs of ownership." The suggestion has been made that the method of issuing owners' cards be changed to the extent of requiring the applicant to bring the car to be registered to the headquarters of the Secretary of State in order that some physical proof of ownership be offered.

Device for Teaching Driving.

Several months of successful operation of a double steering wheel car by Bishop, McCormick & Bishop, of Brooklyn, N. Y., have supplied the comforting assurance that a day is coming when embryo motorists will learn the art of driving with much greater safety to themselves, to other motorists, and to the general public.

The double steering wheel device shown herewith permits the instructor to retain control over the car at all times, even though the pupil is doing the actual driving and gear shifting. This arrangement enables the pupil to try his hand almost immediately on traffic-ridden streets, with the result that he is

Steering device enabling teacher to retain control over car.

far better equipped to drive alone after one or two lessons than the average new motorist is after three or four. The instruction car is not only equipped with two steering wheels but with two sets of brake and clutch pedals. Because of this arrangement both instructor and learner feel a confidence that cannot exist when there is a single control in unskilled hands. The nervous strain that is eliminated can best be appreciated by those who have been through the experience.

The Brooklyn firm precedes this instruction by a series of lessons in an "anchored car", which is set on a platform in such a way as to leave the wheels free. In front of the car is a semaphore with which the instructor flashes signals to the driver. "Sharp turn," "steep hill," etc., direct the pupil to manipulate his controls accordingly, while a special brake lever enables the instructor to produce practically the same conditions as would result on the road. Both the dual control and the anchored car were originated by Bishop, McCormick & Bishop and patents have been applied for on each.

MOTOR TRUCK ENGINES.

What Constitutes Long Life and the Proper Design to Secure It.

From John Younger at the recent Cincinnati Meeting of the A. M. of Mechanical Engineers.—The question of life in a motor truck engine is naturally one which the engineer must compromise. An intense search after long life, to the exclusion of everything else, would result in a monstrosity which would be too heavy, too bulky, and too costly to run.

An approximate definition of long life would, therefore, be "that length of life which is something more than the average expected life, based on present day knowledge and all around conditions."

At the present day a life of 50,000 miles, without overhaul, would be considered long. This would correspond to a continuous run day and night for 12 months, at a speed of about 400 r.p.m., with no attention beyond oiling and fueling. The load will fluctuate between less than zero (as when in coasting downhill with clutch in, the chassis drives the engine) to the full power of which the engine is capable. The majority of the hauling will be done at an average of one-third full engine power. An engine should be capable of at least five or six overhauls, or 300,000 miles, before renewal of the major parts.

This does not look at all severe to the casual glance of the power house engineer, but when one considers that this power plant is operating under widely varying temperatures, power and speed conditions, and that its various axes are constantly changing relatively to the bed to which it is fastened, it will be seen that the problem of long life is not so simple as it looks.

Long life depends on three factors: (1) Design, (2) manufacturing excellence, (3) operating conditions.

Design.

This may be considered under headings such as: (a) Bearing surfaces, (b) lubrication facilities, (c) materials used, (d) factors of safety, (e) general design and use of governor.

Explosion Pressure.—All calculations should be based on full load, not on average load. This can be taken as an explosion pressure of 300 pounds per square inch on the piston with a 22 per cent. compression volume.

Connecting Rod Bearings.—The pressure per projected square inch should be about 700 pounds per square inch, excluding area of oil leads and fillets at ends, or 1 square inch per 2.33 square inch of piston area.

Oil is conveniently introduced through a hole in the crankshaft, and the bearing may either be grooved with a slightly spiralling oil groove around the whole circumference, or a groove around the bottom half only, or a series of slots or labyrinth checks on the sides, or even no grooves at all. Any of these methods prevent ridge wearing on the crankshaft.

The bearing itself should be a thin shell of hard babbitt metal about 1/32 inch thick, backed up by a thick shell of hard bronze running on a case-hardened or otherwise hard surface. This gives the advantages of the babbitt as a bearing metal, and prevents it from pounding out. The bronze should be carefully turned and have peg holes in it to give perfect union between the two. The running clearance should be small, between 0.0015 inch and 0.0025 inch, satisfying practically all truck engines. The split surfaces should be carefully fitted together to prevent rocking or cater-cornered work.

Gudgeon or Wrist-Pin Bushings.—Owing to the slight oscillatory motion, pressures may be higher. Under the conditions of space and the necessity for keeping down the weight of reciprocating parts they may be as high as 1,800 to 2,000 pounds per square inch (or in square inch per 6 square inches of piston area).

Lubricating oil should be brought by a small tube (where pressure lubrication is used) direct to the bearing and allowed to ooze out. The majority of bushings are at present lubricated on what might be called the "chance" method—the chances being, however, chiefly against. The metal should be a very hard chill cast phosphor bronze, running on a case-hardened steel surface.

Running clearances should be kept exceedingly low, 0.00025 inch being satisfactory. Very little tolerance should be allowed.

Pistons.—The side bearing pressure is low, inasmuch as the facilities for lubrication are poor. Sixteen pounds per projected square inch is satisfactory. The piston should be as light as possible consistent with strength, so as to minimize the loads due to the reciprocating masses.

Three rings above the gudgeon pin are ample. They should be thick radially, and preferably of the concentric type, to even the pressure on the slots and prevent them wearing away. A pressure of about 10 to 12 pounds per projected square inch is ample to keep the rings against the cylinder walls.

The piston should be made of a softish gray cast iron, running against a harder cylinder metal. The clearance should be great at the top to allow for expansion due to heat, being four times the piston diameter in thousandths above the top ring, and equal to it in thousandths on the skirt. This bearing surface is, as a rule, relieved around the gudgeon pin.

Cylinders.—Cylinders should be of a hard, close-grained, high tensile strength cast iron. Its scleroscope hardness (though this is of doubtful value) will be found to be about 35. It should be made thick enough in the walls so that actually about 0.006 may be ground off the diameter to take care of wear, without causing weakness. For a 5-inch bore cylinder, 5/16 inch walls are sufficient.

Crankshaft.—Three bearings—front, center and rear—are considered ample for a four cylinder truck engine. Consider the area of the connecting rod bearing (big end) as 1, then the front and center bearings may have an area equal to 1 and the rear bearing 1.5. If splash or trough system of lubrication is used, the areas of the front and center bearings should be increased to about 1.12.

An approximate rule for the diameter of crankshafts in the usual sizes of motor truck engines is that the square of the cylinder bore shall be twice the cube of the crank pin. This gives a 2-inch shaft for a 4-inch bore engine, and about a 2 5/16-inch shaft for a 5-inch bore engine.

Running clearances lie between 0.0015 and 0.003 inch, depending somewhat on the nature of the lubrication.

Digitized by Google

The bushings should be similarly constructed to those on the connecting rod big ends, except that the spiral oil groove will probably be found preferable to give a continuous supply of oil to the connecting rod bearings.

The material should preferably be about 0.40 to 0.50 per cent. carbon steel, carefully heat treated to give a tough, hard surface (scleroscope 36 to 40). The larger diameter shafts should have a percentage of chromium and nickel to ensure better heat treatment and resistance to fatigue.

Low-carbon, case-hardening material is sometimes used, but the shaft has to be increased in diameter to compensate for the lessened resistance to fatigue.

Good-sized fillets, no machine tool scratches and general smoothness of outline will materially help long life.

Camshafts.—Camshafts should be made of low-carbon steel, case-hardened on the wearing surfaces. The bushings should be of a good grade of phosphor bronze. Three bearings are ample for a four-cylinder car. The diameter of the shafts should be from 1 inch to 1⅛ inches, for the sake of smooth operation. The projected area of the bearings, front to rear, should be approximately 4 square inches, 3 square inches, and 2 square inches, depending somewhat upon whether oil pumps or governors are driven from the camshaft.

Valves.—The cams operating the valves should be so designed that just before the valve seats itself the velocity will be considerably diminished, allowing the last few thousandths of its travel to take a comparatively long time. This prevents the valve hammering on its seat. It does not interfere with the fuel economy or power, but gives quieter action.

A 45-degree valve seat is advisable, as carbon will not be driven into the seat, but will more easily clear itself.

Valves containing a percentage of tungsten from 2 per cent. upwards are most satisfactory as regards life and freedom from warpage. By scleroscoping them while hot, they will be found to hold a hardness of over 40. Cast iron remains about 30, while other steel and nickel alloys drop to 25 or lower. The tungsten valve has thus a reason for its long life.

Sundry Parts.—The rest of the engine should be designed in proportion, such as wide faces on the timing gears and ample bearings for their spindles. The water pump should have ample bearing area, and if of the centrifugal type proper, provision should be made for the thrust of the blades.

Studs may be used for fastening down the cylinders, but they should have a length equal to twice their diameter screwed into the aluminum alloy, if such be used. A coarse thread is necessary, but for all purposes where aluminum is concerned, best results are obtained by the use of through bolts.

Lubrication.

Considerable change has taken place in this in the last few years, although even yet all questions have not been settled, and cylinder lubrication is still somewhat on the hit and miss principle.

The method most in favor at present is to carry a supply of oil, about one gallon, in the crankcase of the engine, and pump it under a pressure of anything between 2 pounds and 20 pounds per square inch to a header pipe, from which issue leads to the crankshaft main bearings, and often the camshaft and timing gear bearings. The surplus oil is by-passed by a regulating valve back to the crankcase. This oil and that which has done its work in the cylinders and crankshaft and various bearings drains down to the bottom of the case through a strainer and thence into the pump to renew the circuit.

When the oil gets dirty enough—or say every 300 miles or so, it ought to be thrown out and replaced with clean oil.

The system described works surprisingly well when it is considered that a certain amount of gasoline filters past the pistons and dilutes the oil—that some of the aqueous products of combustion also get past and help form an emulsion.

However, it can only be a matter of time before the adoption of some much better system of introducing fresh, clean oil to each bearing in predetermined quantities. Many oils are on the market and most of them are good.

Incidentally, as a point of design, it should be made easy for the driver to make sure that his oil is in good condition and of ample quantity.

Materials and Factors of Safety.

Naturally extreme consideration has not been given to weight, as has been in the case of aeroplane engines, when 2½ pounds per horsepower has been reached. A fair weight for a motor truck engine is nearer 20 pounds per horsepower at a piston speed of 1,000 feet per minute. Aluminum is used for the crankcase and its covers. Cast iron is used for the cylinders and pistons. 0.40 to 0.50 carbon steel is used for the crankshaft and connecting rods. Case-hardening steel is used for the camshafts, valve tappets and gudgeon pins.

In order to ensure the proper factor of safety being maintained, it is advisable to scleroscope each part for correctness of heat treatment or hardness. Forgings like connecting rods, camshafts, crankshafts, should be straightened before machining.

The general design should be such that extreme climatic conditions can be guarded against. Roads, for example, in winter time are exceptionally bad, causing a weaving of the bed of the engine as would correspond to one of the wheels being lifted 12 inches off the road. The engine should be mounted so that no stress due to this will come on the moving parts.

The engine power should be ample for its work. Too much gear work is detrimental to long life. The transmission reduction should be such that the great majority of road work should be done on high gear. For instance, the hilly city of Cincinnati requires a lower transmission ratio than would the comparatively level cities of Buffalo or Cleveland. This prevents the engine from working at maximum capacity for too much of the time.

Speed should be carefully limited. A maximum piston speed of 1,000 feet per minute is desirable, and drivers and purchasers should be educated to the economy of a governor which will enforce this. The governor should be so designed that it will not restrict the power, but should go in or out of action with a maximum of 5 per cent. variation in speed round the predetermined point.

Too much stress cannot be laid on this. Poor workmanship cannot be tolerated in an internal com-

Digitized by Google

bustion engine. Cylinders should be ground to a maximum tolerance of 0.002 inch, as should pistons, and in addition a process of selection must be used which will ensure pistons on the high limit being put into cylinders of the low limit. The running clearances should not vary by more than 0.002 inch.

Piston complete, should be weighed, the maximum variation in any one of a set being not more than ½ ounce. Similarly, connecting rods should be weighed and balanced, the variation in one of a set being not more than ½ ounce, with the ends varying also by as little.

Connecting rod and crankshaft bearings should be selected so that a maximum variation from standard running clearance of 0.001 inch plus or minus should be adhered to.

There is some diversity of opinion as to the best way to finish these bearings, but the writer believes that a reamed bearing is superior to the usual hand-scraped one. Reamers mounted on a rigid bar will true up crankshaft bearings in a way impossible by the hand reamer. Further, the surface left is as nearly round as possible, corresponding to that of the ground crankshaft. The personal element in hand-scraping is entirely eliminated.

Crankshafts should be ground smooth with a maximum variation of .0015 inch in diameter and 0.001 inch eccentric. Each shaft should be scleroscoped at every bearing. Similarly with the camshafts, pump and magneto drive bushings and so forth, a uniformly high standard should be insisted on.

It follows naturally that rotating parts should be put in static and dynamic balance.

When the engine has been assembled, it should be placed on a stand and run in. Here again opinions differ, but the writer believes a run of at least 30 hours, at a piston speed of about 800 feet per minute, varying the load from zero at the start to practically maximum for one or two hours at the finish is necessary.

Most of this test, if indeed not all, should be done with some kind of fuel, either gas or gasoline, to get the engine thoroughly warmed up. This will ease off the high spots, let the valves find their seats, and generally take the harshness out of the engine.

At the end of this run, the engine should be partially disassembled and valves reground, piston rings touched up, carbon cleaned and the engine carefully inspected for signs of wear or scoring flaws.

When reassembled, the engine is ready for work.

Operating Conditions.

One of the secrets of success in gasoline engines is oil and lots of it. After a comparatively short run, the oil (in the average system) is contaminated by gasoline and carbon. It should be drained out every 150 to 300 miles and replaced entirely by fresh oil.

The strainers leading to the pump should be kept clean and inspected frequently.

About once a month the whole engine should be cleansed by washing it out with kerosene, turning the crankshaft by hand and thoroughly draining the kerosene all out.

Screens should be provided on the air intake to the carburetor to prevent entrance of road dust as much as possible.

Gasoline should be cut down in the carburetor as much as possible, not only for the sake of economy in consumption, but also for the prevention of harmful effects by an overplus.

The point of ignition should be properly controlled so that evils following an "advanced spark" will not result.

Drivers should change to a lower gear immediately there are signs of the engine laboring.

Drivers should be carefully selected and trained men. Good horse drivers make good truck drivers, as they are accustomed to giving care and attention to their "motive power."

A regular system of inspection should be carried out by a good mechanic to detect any signs of trouble developing.

It is understood that hilly country or heavy roads will materially add to the work the engine has to do, and that the life will be proportionately shortened and inspection and overhauling will have to be done more frequently.

TIRES AND HEAT.

The Wise Owner Will Look Carefully at the Matter of Pressure.

From H. C. Brokaw, Principal West Side Y. M. C. A. Automobile School, New York City.—Should the pressure of tires be decreased in hot weather? Is it true, as some tire manufacturers claim, that tires heat more on lower inflation than when run at the full pressure given by them? Are tires injured by a slight decrease in the pressure to take into account the increase due to friction and hot pavements?

There have been some criticisms since my relation of an experience with tires while on a tour, in which it was stated that there was a 12-pound increase in pressure after going 40 miles; so I have been checking up and testing conditions in city driving.

Recently, to determine what effect the hot weather has on tires in the city, I drove a 3,200-pound Model L Locomobile, equipped all around with 34x4½ inch tires, through the park and on Riverside Drive for 15 miles at ordinary city traffic speed, which always is under 20 miles an hour. The thermometer registered 86 degrees and the day was partly overcast, so that the full effect of the sun on the pavements was not obtained. The tires were inflated to full 90 pounds, which is the pressure recommended by many manufacturers.

At the end of the run one tire registered 101 pounds, two were 100 and one was 99 pounds. The conditions were not excessive in any way and the weather was not abnormal, the road was smooth except for very short stretches, the speed was low and the tires were of ample size for the weight of the car and load.

After this test, a gauge was made to test the flattening effect on the tires from a lowered pressure. With the car loaded it was necessary to decrease the pressure in the tires to 65 pounds to have 1/16 inch bulge of the side of the tire. At 70 pounds pressure there was no perceptible flattening.

I believe that more tires are damaged by underinflation than by overinflation, also that new tires will stand more than 20 per cent. overinflation without damage to them. But it is reasonable to believe

Digitized by Google

that if a tire has become weakened from any cause that it will blow out quicker under increased pressure. It is also a fact that a tire inflated to the pressure recommended by many manufacturers has very little resiliency and the riding qualities of the car are very greatly impaired, and when the pressure rises slightly higher, the tire loses its chief function, that of absorbing small road shocks. Anyone who has had the experience of riding on hard tires knows the discomfort of it; one might about as well ride on solid tires. But all of this comes back to the question: What is underinflation? A tire with ten pounds less pressure than recommended possibly will heat more than when carrying a full pressure; but it will very quickly come up to the required pressure when in use.

As the pressure recommended by many manufacturers is the extreme so far as comfort in riding is concerned, the car owner must take his choice between comfort and tire mileage, assuming that a slightly less pressure does decrease the life of the tire. I presume the average owner would rather have comfortable riding, even at the expense of tire mileage, and I am not prepared to admit that decreased mileage would be an inevitable result with ten pounds less pressure. I do not think the average man would use a substitute for gasoline which gave him all sorts of discomfort because it did not run the engine smoothly, even if it gave a slightly greater mileage to the gallon.

One manufacturer of fabric tires recommends 56 pounds pressure for a 4-inch tire and guarantees 5,000 miles, and makes the claim that this pressure makes riding much more comfortable. Another well known manufacturer advises inflating the tire only to the point where there is no bulge or flattening, and another type of pneumatic tire has become very popular because it requires still less pressure and makes riding much more comfortable.

Where tires are hard and roads are rough, the machine jumps around so that it is more likely to jump off the road, so that there is an element of safety as well as comfort involved.

For all around comfort, consistent with good tire mileage, I have concluded that a ten-pound decrease in pressure in hot summer weather is desirable. The tire cannot be damaged because after a very few minutes on really hot pavements the pressure will equal that recommended by the most exacting manufacturer and any overheating due to this cause would be a matter of very short duration.

As I said in a previous article, the wise owner will test out his car and tires and find out just the proper amount of decrease the tires will stand. As a matter of fact, I have done considerable riding with a tire salesman, one of the fellows who is quite insistent upon a certain pressure, and it was his invariable practice to deflate his tires ten pounds in hot weather, notwithstanding the fact that he was after tire mileage.

All of which goes to show that some people do not always take the advice that they give.

Sound Death Knell of the Cut-Out.

The members of the National Automobile Chamber of Commerce have voted unanimously for the elimination of muffler cut-outs on the cars they build in future, so far as they can be operated from the driver's seat. With more than four million cars in use and supplying a great service in the transportation of the individual and of materials, the use of muffler cut-outs is held to be unfair to the public and to add an unnecessary noise to American life. Cars have ample power so that the slight increase in speed which may come from the use of cut-outs is of no importance. There may be times in adjusting motors where a cut-out is useful, but in such cases, it can be operated from under the car.

Almost half of the 110 makers in the Chamber do not fit muffler cut-outs to their present cars and all makers voted that they should be eliminated in the new products. The directors at a recent meeting adopted the following resolution:

"Whereas, Members of the National Automobile Chamber of Commerce are opposed to the attachment of muffler cut-outs to motor vehicles and do not fit them to the cars and trucks they manufacture, or will discontinue doing so on their product for 1918; and

"Whereas, The use of the cut-out is unnecessary, annoying and dangerous to other users of the highways and objectionable to residents along them,

"Resolved: That the Board of Directors recommends that all members of the National Automobile Chamber of Commerce refrain from attaching muffler cut-outs to their cars for the season of 1918 and thereafter and that no cars be sold by them after January 1, 1918, with cut-outs attached, or that where cut-outs are attached they be made inoperative from the driver's seat."

Government to Aid States Build Roads.

According to the Secretary of Agriculture the government has appropriated $14,550,000 to be used in the fiscal year ending June 30, 1919, by the several states in the construction and maintenance of rural post roads as follows:

Alabama, $313,456.47; Arizona, $205,540.58; Arkansas, $250,018.47; California, $456,167.23; Colorado, $257,278.92; Connecticut, $92,216.45; Delaware, $24,411.99; Florida, $170,723.88; Georgia, $403,909.45; Massachusetts, $221,261.85; Michigan, $435,356.37; Minnesota, $425,865.40; Mississippi, $268,751.60; Missouri, $508,603.98; Montana, $298,520.89; Nebraska, $319,445.25; Nevada, $193,229.82; New Hampshire, $62,610.11; New Jersey, $177,357.22; New Mexico, $238,634.55; New York, $749,674.20; North Carolina, $342,556.47; North Dakota, $229,585.91; Ohio, $558,043.42; Oklahoma, $346,489.34; Oregon, $236,332.74; Pennsylvania, $690,145.78; Idaho, $182,471.55; Illinois, $658,323.48; Indiana, $406,230.18; Iowa, $434,653.61; Kansas, $429,131.88; Kentucky, $292,984.62; Louisiana, $203,755.29; Maine, $144,807.42; Maryland, $130,871.43; Rhode Island, $34,972.38; South Carolina, $215,014.08; South Dakota, $243,175.61; Tennessee, $340,663.51; Texas, $876,986.70; Utah, $170,763.17; Vermont, $68,128.92; Virginia, $298,120.77; Washington, $216,530.19; West Virginia, $159,713.89; Wisconsin, $382,707.20; Wyoming, $183,805.78.

This is the third apportionment under the act, $4,850,000 having been apportioned for the fiscal year ending June 30, 1917, and $9,700,000 for the fiscal year ending June 30, 1918.

The most stylish color for autos is invisible gray, the only trouble being that the salesmen demand a visible green in exchange.

STOP! LOOK! LISTEN!

Car Drivers Show Amazing Recklessness at Grade Railroad Crossings.

This magazine has arrangements for receiving brief outlines of the serious automobile accidents in the United States and not a day passes that a report of some fatality at a grade crossing does not materialize. Riding out through the country, it is astounding to observe the chances taken by car drivers. The practice of stopping the car at a grade crossing seems to be far more "honored in the breach than in the observance." Making a rather close estimate, we believe more deaths occur from automobile accidents at grade crossings than from all other sources.

Reminders, warnings, examples, precepts, seem to have no effect whatever. And more than this, a railroad official is authority for the statement that out of every hundred persons killed or injured at grade crossings, nearly half are occupants of automobiles. In one instance, a person was stationed at an important crossing and he learned that of 923 automobiles, 801 car drivers did not look in either direction when or before crossing the tracks. Only 83 drivers looked one way only, and but 39 looked both ways.

It is a strange thing, but nevertheless true, that many persons who are not ordinarily reckless will approach a railroad crossing and drive over it, placing their lives entirely in the hands of another human being, whom they know has been placed on the crossing to warn them, whereas the simple precaution of looking for themselves, which could be done with scarcely an effort, would insure them against a mistake which might be made by the flagman. In one case in particular which a railroad official investigated a man drove onto a railroad crossing where there was an automatic bell to give warning of the approach of trains. He was struck and severely injured. There seemed to be no question in this case but what the bell was out of order and did not ring, but the man afterwards admitted that he did not take the precaution to stop, look and listen because he depended upon the bell entirely.

In other words, he permitted the safety of his own life to rest entirely upon a mechanical contrivance, ignoring the possibility that it might not be in perfect working order. Of course, the bell was installed there to warn travelers on the highway, and it was expected to perform that function. However, something went wrong with it as might, indeed, happen to any machine. The slightest effort on his part, had he followed a habit of ordinary care, would have meant absolute safety in this particular instance.

Another time the same official listened to a complaint made by a man against an engineer because the engine whistle was not blown for a crossing. Yet, it was not long after that the man who made this complaint was seen to drive carelessly over the same crossing without paying the slightest attention as to whether it was safe for him to cross the tracks or not.

Railroad crossing accidents are sometimes contributed to by the fault of a railroad company or its employes, but whether they are or not it is unquestionably true that the great majority of these accidents can be avoided by ordinary care on the part of the motorist. Many of the accidents are caused merely through the failure to stop, look and listen. There are some, however, that occur because of sheer recklessness.

In one case a railroad official had occasion to investigate a case where an automobile was driven along a country road which ran parallel to and directly alongside a four track railroad. A freight train was going in the same direction as the automobile on the track nearest the roadway. The automobile passed the freight train, and at that moment reached a bend in the road where it turned abruptly and crossed the tracks at right angles. Instead of waiting for the freight to pass, the driver of the automobile spurted forward and crossed the first track perhaps a hundred feet ahead of the engine of the freight. He would have gotten over safely but he did not count on the possibility of a train on the second track. As it happened, a fast passenger train running in the same direction as the freight and obscured from view by the freight was approaching on the second track, running sixty miles an hour. This train shot by the freight and reached the crossing before the automobile could clear the second track and the result was the automobile was struck and two of the occupants instantly killed.

In this case the driver wanted to "beat out" the freight train and get over ahead of it. He simply took a chance and lost. This is a fair illustration of the manner in which persons will take chances to save a few minutes time. Such chance taking is merely a form of gambling. If a man bets on a horse to win a race, he puts up his money as a stake and takes a chance that his horse will win and that he will gain a few dollars. If you drive your automobile over a railroad crossing and do not stop to look and listen, you put up your life and the lives of others who may be in your car as the stakes, and you take a chance that no train or engine will happen to strike you and that you will win and gain a few minutes time. In other words, it is a gamble to save a minute's time with human lives as the stakes.

On occasions I have ridden with friends or acquaintances, and have held my breath as the machine was driven over a railroad crossing without the slightest effort to ascertain if the way was safe. It just happened that no train was approaching nearby. But what if fate had played a different hand and there had been a train? It is a thought to make one shudder. It is in just such manner that many have gone to death or serious injury, while just a little caution—just a moment's stop, a careful look up and down and a moment of listening, so easy to have done—would have made the way safe for the automobile party.

First, last and always the rule of "stop, look and listen" before crossing a railroad should be faithfully observed, no matter whether it is a protected crossing or whether it is an unprotected crossing in the open country. If every automobile driver would paste this rule alongside his speedometer where he can never fail to observe it, this class of automobile accidents would be almost entirely eliminated.

Someone has said: "It is a good thing to learn caution by the misfortune of others." There is a world of advice in that short sentence. Automobile owners and drivers can find only too many unfortunate examples of misfortune due to absence of cau-

Digitized by Google

tion by reviewing the accidents that have occurred on grade crossings. May the lessons taught by the bitter experience of others sink deep into the minds of every driver of a car, to the end that caution at railroad crossings—just the ordinary, easily exercised self caution of stopping, looking and listening—will prevail, and many of these lamentable accidents will be prevented.

CAUGHT ON THE "FLY."

A Stranger Who Said His Automobile Bearings Had Melted.

From J. N. Bagley, Nebraska.—On the other side of a seemingly endless chain of hills, known as "The Whiterock Hills," runs the marked trail close to the boundary line of the State. Here we found a beautiful shady nook where the wild flowers had woven their lovely patterns for an eastern carpet. The springs set in tanks of moss and fern held that clear cold water which had no doubt cooled the fevered brow of many a weary and careworn traveler in days past. Here we had prepared to rest until the morning before attempting to resume our journey, for we were weary, and judging from the tents that were visible from our camp many other tourists had decided to do the same. At supper time could be seen many curling smokes from camp fires, and many happy voices rang and echoed from hill to hill. Together in little bands they would watch the light of the setting sun fade from the summit of some prominent peak far to the westward.

Not infrequently there were accidents along the trail, and occasionally some reckless driver would plunge his car over the embankment, but there are always many willing hands to help and to lend such parts as are needed to make repairs. The men that hovered about the camp fire were discussing some of these experiences when their meeting was interrupted by a motor car a little way off running very slow, but pounding until it could be heard for some distance. The unfortunate traveler came close to the camp and stopped his car.

"Hello, boys," remarked the stranger. "Are there any mechanics in this bunch?" He was told that we were all mechanics and to just state his case. He told us he had melted his crank bearings. At once we all decided he must have overlooked his oil and questioned him about it, but found that he had placed a quantity of oil in his case only a few miles back. We examined the oil level and found oil enough. Why the bearings had melted we were at a loss to understand, but set about to find the cause if possible.

Some one suggested that we remove the oil from the case and examine it, which we did. We found the oil to be very thin, having a kerosene smell to it, so we placed a little quantity of it in a vessel and lighted it. The oil burned quite readily, which indicated it was a very low grade of oil and not intended for automobile lubrication. The fact of the matter was that our friend supposed he had been economizing, for he had purchased a quantity of oil from some traveling oil peddler. He had filled a large can that he happened to have with him only a little way out of the town of B. We asked him why he did not purchase the oil at the garage as he came through, and he said that the salesman told him that the oil was the same as the garage man sold. In fact, he sold the garage man, but he would let him have it at cost, which was very cheap, of course, compared to the price the dealer must pay for a good oil. Instead of reducing the cost of traveling, our friend had added an unnecessary expense to his bill, which amounted to a good many dollars.

This illustrates how essential it is that the oil used in the motor should be only the best, and should be purchased from the local dealer who is responsible. The man who peddles oil about the country to the consumer direct usually has a very low price and a very low grade of oil.

It is a hard matter for a person to judge the oil which he uses. In fact, he can only depend on the company of which he buys to get the product he wants, and they can give him what they like. Consequently he trusts to their honesty in every instance when he buys his oil. We are not protected as we should be by law when it comes to lubricating the motor car. There should be a law compelling every concern handling oils and selling to either the jobber or the consumer to give a test of their oils on the package or barrel, whichever it be. This would cut out some of the fellows who are selling "dope" and labeling it oil and ruining many motor cars.

The first thing the motor car user should do after buying his car is to become familiar with the parts to lubricate and the kind of oil or grease adapted to the particular place, and see that nothing be substituted.

As to the kind of oil for the different seasons of the year, there is some difference of opinion among users. Some prefer a heavy oil and some prefer a light oil, but for my part I look more to the quality of the oil than to its body, for when the oil is subject to the heat of the cylinder it must become as thin as kerosene and it does not matter whether it is heavy or light. When it is heated it will all be about the same.

Many have asked me what the flash test meant, and how it was obtained, and if it had anything to do with the lubricating properties of the oil. It does, of course. To obtain this test, place a quantity of oil in a small basin and place it over the fire and heat it until it gives off a smoke. Now pass through this smoke a flame and the smoke will seem to flash and take fire immediately. This is the flash test. The degrees of heat at the time the smoke is given off in this instance will show the flash test of the oil, but, of course, to make the test it will be necessary to have the necessary equipment, and not many have it, or could use it in case they did have it. Now if we continue to heat the oil beyond the flash test we will get the burning point shortly afterward. When the oil has reached this stage, it would not do much lubricating but would burn and pass away in smoke. It is, therefore, very readily seen that an oil lacking these two things would not be a good oil to use in an automobile engine. The flash test must be taken into consideration.

A test for acid in oil can be made in different ways, but a very simple one is to take a wick and saturate it with oil and lay it on a polished steel plate out in the sun. After it has been out a few hours, remove the wick, and if the plate is just as it was, there is no acid in the oil, but if the plate

Digitized by Google

has dark spots it indicates without a doubt there is acid in the oil and it should not be used for lubrication of the engine.

Another test for acid in the oil can be made with litmus paper. Take a small piece of blue litmus paper and dip it into the oil, and if there is acid in it the paper will at once turn to a pinkish color. Either of these methods while simple are practical and can be relied upon.

Over lubrication will cause trouble just as much as a scant amount of lubrication. Too much oil will find its way into the muffler, clogging it up and making the interior of it very gummy and sticky, which tends to cause the motor to overheat. It also causes a carbon deposit on the piston heads and valves, causing the valves many times to stick in their guides, thus affecting the working of the motor to such extent that it is necessary to take it down and clean it thoroughly. This deposit at first becomes gummy and as it becomes heated it finally gets hard, and can hardly be scraped off. These particles of carbon after getting hard will be heated red hot and cause what is known as pre-ignition; that is, the charge is ignited before the piston has reached the desired position, causing a knock in the motor. This knocking is very injurious inasmuch as it causes a strain on the working parts of the motor, for the momentum of the flywheel must carry the piston over the center against the pressure of the burning charge of gas that has been ignited by the hot particle of carbon.

When there is too much oil it indicates that the reservoir is too full, or the oil feed is not adjusted properly, and many times a heavy oil replaced with a lighter will remedy the cause. The old two-cylinder engines, which are little used today, used to have what we called a baffle plate to keep an oversupply of oil from getting into the cylinders, and when one of these came loose the oil was splashed into the cylinders until they would hardly run, and if they did run at all they would get hot and have very little power.

Now in case there is a lack of oil, the motor will heat from the friction. The motor will pre-ignite from the heat; the water will boil from the radiator; the motor will pound or knock, and have hardly power enough to run, to say nothing of propelling the car.

When the motor has got very hot with a scarcity of oil, the bearings will either seize or melt out. Many times the pistons will seize in the cylinders and necessitate the taking of the cylinders off to loosen them, and in many instances just before they seize they become so dry that the interior walls of the cylinder is scored to such an extent that they will not be of further use. This one thing makes a very expensive repair.

There are times when the oil pipes become clogged from some particle of waste material getting into the line, stopping the circulation of oil and allowing the dip pan to become dry, in which case the bearings will become dry and melt out. It is not a bad idea to strain the oil that goes into the case and avoid any chance of the line becoming clogged, for the pumps are delicately constructed affairs.

Going back to the beautiful shady nook and the patterns of wild flowers woven into a carpet over the ground of our camping place, we find the stranger again fixed up and ready to resume his long journey westward in search of the beautiful and profound sweetness that exists along the trail. He took a drink from the rock spring that found its way through the moss and fern to an open tank, cast a glance at the ceiling of green that hovered over us, and glided down into the canyon and disappeared. The little camp was broken up, each going his way, and I wondered when or where the next meeting would be.

Chalmers Replaces Leland.

At a recent meeting of the board of directors of the National Automobile Chamber of Commerce, Hugh Chalmers was elected first vice-president to take the place of Wilfred C. Leland, who leaves the automobile industry to enter the airplane industry as one of the owners of the Lincoln Motor Co., Detroit. H. H. Rice, of the General Motors Co., was elected vice-president of the gasoline division.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

2208 Would Use Kerosene for Fuel.

From O. C. Winestock, Vermont.—Can you tell me how hot kerosene must be in order to be used successfully with a gasoline engine with no special carburetor? Would it be necessary to have such a device as close to the carburetor as possible, so that the kerosene would not become chilled? Would it be necessary to take hot air also from the exhaust pipe as is commonly done, supplying the hot air to the intake of the carburetor? I have always felt if kerosene could be heated enough it would be suitable without special carburetors in gas cars.

Reply.—The kerosene must be heated to that temperature that will insure rapid evaporation so that the minute particles of the fuel will be completely broken up and thoroughly mixed with the air. The successful use or rather satisfactory use of straight kerosene with the ordinary carburetor, is yet to be recorded although reports are frequently circulated. Relative to maintaining the kerosene and the resultant mixture, the best results are always obtained when any mixture of fuel and air is kept warm or dry. This is termed a homogeneous mixture, one that ignites readily. With all of the devices now marketed for using kerosene use is made of heat, generally that of the exhaust. The most successful one that has come to the attention of the writer is not marketed. It encloses a Venturi tube within the

Digitized by Google

exhaust manifold which maintains the desired temperature required for successful vaporization of the fuel. Kerosene has not and will never be made to work successfully in an ordinary carburetor in connection with an automobile engine for the automobile engine is a variable speed, variable load engine. Where the load is practically stationary and the speed does not vary greatly kerosene can be used. Very good results are said to have been obtained by using 50 per cent. gasoline and 50 per cent. kerosene. It requires, so it is said, less air.

2209 **A Question of Flexibility.**

From Emil R. Schwandt, Wisconsin.—Will you please tell me if a Knight four-cylinder engine is more flexible than a four-cylinder engine (poppet valve) of the same horsepower? Is the Knight more flexible than a six-cylinder engine of the ordinary type? Has it any advantage or disadvantage over the common type of engine? Has it any drawbacks or is it almost a perfect engine? Will they outwear the ordinary engine and can the cylinders be rebored?

Reply.—There appears to be no reason why the Knight engine should be more flexible than a poppet type of valve of the same given bore and stroke. Some engines are more flexible than others. The Knight is not more flexible than a six-cylinder engine for the simple reason the six has more impulses a crankshaft revolution than the four-cylinder. Several claims are made for the Knight, the most noticeable of which is that valves are eliminated. One advantage is that there are no valves to grind or mechanism to adjust. Quiet operation is another feature of the Knight engine, but equally as quiet valve type engines are made. As to what constitutes a perfect engine, Knight or otherwise, there appears to be a considerable difference of opinion among engineers. Some claim the 12-cylinder is the best while others favor the eight. And again the six and four-cylinder types have their advocates. Much ink has been used by engineers in defense of their favorites, so our opinion as to the perfect engine would be but adding to the controversy. The cylinders of the engine referred to can be rebored.

2210 **Another Lighting System Trouble.**

From E. H. Madge, California.—I am experiencing great difficulty in getting the generator of my car to charge the battery. At times the ammeter will show charging all right and then suddenly it will stop charging, showing zero. If I open up the engine on the loose clutch, it will indicate charging and sometimes for quite a few miles. Then it will again drop off. The generator has been thoroughly overhauled, the commutator turned and new brushes fitted and still this occurs. It has been taken to pieces to detect the cause and by some accident in connecting up, the charging was regular. Of late, however, the above again happens. I should like some information regarding this.

Reply.—The trouble may be inside the generator or between the generator and the battery, to tell in which circuit the trouble is located, run the engine at different speeds until the ammeter shows zero, then connect the voltmeter across the generator terminals. If it shows a very high voltage, the generator is "O.K." and the trouble is between the generator and the battery. Look for loose wires or a broken wire under the insulation. Also examine the cut-out and see if it is closed. If not, push it closed with your finger. If the meter shows charge, the trouble is with the fine winding of the cut-out. If the generator shows a very low or no voltage the trouble is inside the generator, such as the brushes—though new, may not properly fit the commutator—a loose shunt field connection, loose connection in the wires connected to the brushes or terminals, or the trouble may be with the regulator, but as you do not state the make and type of generator it is impossible to state at what point to look for trouble in the regulator.

2211 **Relating to Compression.**

From Adolph Vlk, Illinois.—Is there, for the proper compression of the charge in automobile motors any established relative proportion between the volume of the combustion chamber, when the piston is at top of stroke and when at bottom of same? Should the distributor be timed (spark lever fully retarded) so the spark will occur at the time when the piston is in the uppermost position?

Reply.—If we understand your question correctly we should say there is not. The timing of the distributor of the present battery system of ignition is obtained by causing an interruption of the primary circuit by mechanical means, either the open or closed circuit. Theoretically the break is supposed to occur when the piston has attained top dead center or completed its compression stroke. Some manufacturers so set the timer-distributor that the break takes place with the piston at top dead center and with the timer fully retarded. Others allow a slight advance, or, in other words, the break occurs just before the piston reaches top dead center. This practice is more indulged in than formerly, due to the very general use of the motor starter, the speed of which largely obviates the possibility of a back kick which was so much feared in the days of manual cranking. If you time so that the points of the breaker mechanism separate with the piston at top dead center you will obtain satisfactory results. It is better, however, to learn the exact timing from the maker of the car or engine.

2212 **Is Troubled With Leaky Gearset.**

From Gilbert Zoellner, Wisconsin.—What do you think of patent carbon removers? I have used one in the form of tablets called "Worko". Is this preparation harmful? It seems to clean out the carbon and the motor runs as good as if the valves had been ground and the carbon removed. Do you think Johnson's carbon remover is better than the one I used? I have never tried it. Do you consider them practical? Our garage man said he would not use them but he would not give any reasons why he wouldn't. What is your opinion of the tire covers made by the Colorado Tire & Leather Co., of Denver, Col.? How high should the lubricant be in the transmission of the model 2 S Saxon? If it is carried higher than the top of the lower shaft it works back into the differential housing. Is it proper for it to do this? How often should steam cylinder oil be used? Please explain thoroughly how to grind the valves of the Saxon Six, giving the harmful results

Digitized by Google

that might come from one doing this without any experience.

Reply.—Chemical preparations for loosening and removing carbon have been marketed for some time and if the material used did not injure the engine, and there is no reason why a properly prepared carbon remover should, it is the best answer to your question. Inasmuch as the writer has never used the remover you mention he cannot make any comparison with the other make. But it can be stated without contradiction that Johnson's carbon remover has given perfect satisfaction to a large number of users. Relative to the tire covers mentioned, these have been on the market for a long time and are endorsed by a large number of motorists. If they are not as represented, we have failed to hear a complaint. The cause of leakage of oil in the transmission of the car referred to is probably due to worn bearings. The gearset is in front of the rear axle and when thin oil is used and worn bearings exist, the lubricant will work into the differential housing. It should not do this but it will do no harm. Use a heavier oil than the one mentioned and just enough so that the bottom of the gears dip into it. Renew as often as required or according to number of miles the car is operated. To grind the valves will require considerable preparatory work. The wires to the spark plugs must be removed, also those leading from the timer-distributor to the coil, and the timer will have to be displaced before the cylinder head can be lifted. There is a rubber pipe connecting the cylinder head and the radiator and the fan will have to be removed to take off this pipe. After attending to these details remove the plates covering the valve mechanism, and with the valves seated compress the valve springs so that the divided slip collars can be removed from the ends of the valve springs. These collars set in recesses in the valve stem. To grind a valve its face is smeared with an abrasive—it is best to buy a prepared mixture—and the valve rotated with a screwdriver. Do not exert much pressure and occasionally lift the valve, also turn the valve slightly during the process. Clean valve and seats before renewing supply of abrasive. Continue grinding until you obtain a good seat; that is, until the pits, etc., are removed. Before replacing valves they and the seats should be washed with gasoline, taking care that none of the fluid gets in the cylinders. Make sure that a valve is seated before you begin to grind; that is, there be space between the stem and tappet. You will have to turn the engine over as you proceed from one valve to another. Of course you will scrape the carbon from the cylinder head and pistons and use a new gasket when you replace the cylinder head. If you are not familiar with the timing it is best to mark the wires, also the leads to the coil. In replacing the timer make sure the key of the shaft registers with the slot of the engine shaft and that the locking screw and nut be set up tight. To time, place the piston of the No. 1 cylinder, that nearest the radiator, on top dead center or completion of compression stroke. The breaker points should be about ready to separate and the brush of the distributor opposite the segment to which is attached the wire leading to the spark plug of the No. 1 cylinder. If not familiar with grinding valves it is best to have some expert supervise your work, also the timing.

2213 **Wants to Use Smaller Tires.**

From H. N. Andrews, Massachusetts.—Will you kindly give me your opinion on the following matters in your September issue?—Changing rear Ford tires to three-inch size, having K-W shock absorbers and keeping springs well oiled, load unusually light. Using reverse pedal occasionally as a brake.

Reply.—It would not be practical to use a three-inch tire on the rear wheels for several reasons. In the first place the weight of the car, etc., require a 3½-inch shoe and were it not essential the Ford Company would not spend the money for a size larger than three-inch. Another reason is that the rim is made for a 3½-inch shoe and a three-inch would have to be stretched considerably to go on the rim. We would suggest that you stick to the standard size shoe. The use of shock absorbers and maintaining the springs in a properly lubricated condition will save tires and make for much more comfortable riding to say nothing of eliminating road shocks to the mechanism. Conservative use of the reverse is not harmful.

2214 **Experiences Gasket Trouble.**

From J. U. Blose, Pennsylvania.—I have trouble with water leaking into the cylinders after putting a gasket in for the second time. On page 80 of their book of instructions they say do not remove the sticky composition from the gasket. What is this material? I have used shellac but it is hard to remove the gasket with this material, it sticking to the metal and head. I am compelled to use a new gasket every time I take the cylinder head off to clean out carbon.

Reply.—Inasmuch as you did not state the make of car it is difficult to advise you as to the material referred to. There are several compounds marketed for the purpose you mention. The using of the old gasket for the second time is not to be recommended. In the first place it is not always easy to displace it without injuring it, and besides the new gasket saves considerable time and labor. It may be that you failed to clean the cylinder head and top of block carefully before replacing gasket.

2215 **A Battery Charging Question.**

From C. L. Weygandt, Illinois.—A storage battery man recently told me my battery was holding a full charge too long and advised me to burn the lights during the day for about 4 hours while the car was in the garage. I do most of my driving at night and keep up a speed of 12 to 15 miles per hour with the lights burning dim, the battery showing charge while so driving. The car has been driven 3800 miles since January and the battery, a Willard, has never been recharged. Another battery man advised me to allow all the charging possible and informed me there was no danger of over-charging. Is there danger of over-charging and what shall I do?

Reply.—An overcharge of a battery is held to be beneficial and it is better to slightly overcharge than undercharge. The condition of your battery can be easily determined by yourself by the use of a hydrometer with which readings can be taken of each cell. Complete instructions accompany the instrument, which is easy to use. The fact that you have been using the battery over eight months and it is giving good service is a good indication

Digitized by Google

that your present system is a good one. When in doubt drive up to the nearest Willard service station. Its expert will advise you fully and test your cells. That's what he is there for.

2216 **Several Electrical Problems.**

From Jacob A. Rettig, Indiana.—I have a 1915 Allen No. 34 model touring car. It leaks and lets grease out on the rear axle, and the brake doesn't hold. I have put felt washers on at two occasions but they never last long, and it will let grease out again. I also put one on a Ford car without success. 2.—The machine has a Westinghouse generator and a volt meter on it. It used to register up to 7¾ to 8 volts at about 25 miles speed, and at 15 miles an hour it would show about 7¼ to 7½ volts, but now it only shows from 6½ to 7 volts. The brushes show a glaze and not oily. 3.—How long do spark coils in a Ford machine last? Do they burn out or how can you tell when they aren't any good? Also how can you tell whether the trouble is in a magneto or spark coils? For what purpose is a spark coil on a machine? I am a blacksmith and will have to take up this work some day. Could anybody learn this trade through Correspondence Schools, or would he have to go to an auto school? The electric system is what puzzles me most of all.

Reply.—1.—Felt washers of the right material and fit if properly installed should remedy the trouble mentioned. If they fail we would advise taking the matter up with the maker of the first named car. 2.—The slight falling off in the output of your dynamo is not sufficient to cause any worry, providing the generator keeps the battery properly charged. If not it will be well to have the service station man look over your cut-out. 3.—The life of a vibrating type of spark coil such as used on the Ford varies considerably. There is no well defined life to these coils but if properly cared for should outlast the machine. In another section of this issue will be found a very comprehensive description of the ignition system of the Ford car and how to locate and remedy troubles. The object of a spark coil with a jump spark system of ignition is to build up or strengthen the primary current, or in other words, to so intensify it that it will bridge the gap of the electrodes of the spark plug. A course at a school would be a great help as you would become familiar with the principles of construction, etc.

2217 **Testing Magneto.**

From H. D. Pierce, New York.—I have a Bosch DU4 magneto that I cannot get a spark from. It has been on a Studebaker 20, fastened down with a strap and a nut, the same as the old low-tension Splitdorf. It was running fine at a car speed of not over 20 miles per hour on high when it began to miss an occasional charge. It ran a short distance on a level road. I had to drop back into low speed. The car ran a few yards and stopped entirely. I have tried an ammeter and dry cell of 20 amperes and cannot get any current from the armature core to the slip-ring. Am I right in thinking the coil has broken down? And what would cause this trouble? I have been careful not to damage the magneto when taking out the armature shaft and placed a keeper over the pole shoes while it was out of the magneto. Which way should the breaker arm run on a clockwise DU4? I have two cars, one with a magneto running clockwise and the other anti-clockwise and think them both wrong according to illustrations.

Reply.—The test you made does not necessarily prove that the winding is broken as the resistance of the secondary winding is too high to show any deflection on the ammeter. If you have a sensitive ammeter of low scale connect it in series with five dry cells, then touch one end of the battery lead to the magneto frame and the other side of the meter to the collector ring. If you get a deflection it shows that the winding is not broken. Place a piece of paper between the interrupter points and touch one side of the battery to the stationary interrupter point and touch the wire from the other side of the meter to the frame. If you get a deflection the primary winding is not broken. Examine the insulated interrupter point to see that it is not grounded. Make sure that the platinum contact points of the interrupter mechanism be clean, true and the break not over 1/64-inch. If the test of the safety spark gap fails to show a spark, it is best to take the magneto to the nearest service station of the Bosch Magneto Co. It may be possible that your magnets have become affected through an accident, such as a hammer or wrench striking them. The majority of magnetos, particularly the Bosch makes, are marked as to the direction of the armature shaft by means of an arrow. They are made to run clockwise unless ordered otherwise. This means that the armature shaft revolves clockwise when looking at the instrument from the driving end. When thus viewed the breaker member you refer to rotates clockwise with a clockwise instrument, but if you look or face the breaker box end the shaft and breaker mechanism will, of course, rotate anti-clockwise. The anti-clockwise magneto when viewed from the breaker box end would appear to have a clockwise breaker mechanism. You will avoid confusion if you bear in mind the direction according to the driven end of the instrument.

2218 **Would Change His Carburetor.**

From W. F. Ferguson, New York.—I have a Ford car equipped with a Holly carburetor. In my work I have unusually steep hills to go over and the engine sometimes stalls and I have trouble in climbing the hill. In an automobile instruction book I note it says that a model R Schebler carburetor with a special manifold is made for Ford cars. The valve of the manifold is controlled from the dash. Do you believe if I installed this carburetor I would get better hill climbing capacity out of my car? Could you furnish me with the price of the carburetor and where obtainable?

Reply.—Whether or not you would obtain better results by changing your carburetor depends upon the condition of the present one and how the make you mention would work on your engine. If your present carburetor is an old one it may not be adapted to the present heavy grade of fuel; that is, the best results cannot be obtained with it. There is no reason why your car should not surmount the steep hills you mention, particularly on the low speed. If the car has been in service for some time we would suggest that you go over the engine thoroughly and see if the valves are seating properly. Also make sure that none of the brakes are dragging as these frequently are the cause of lack of power.

Digitized by Google

If adjusting the carburetor fails to give you the results you desire you might try a more modern type. There is no reason why you cannot install the carburetor you mention. Generally carburetors for the Ford include a special manifold which is easily attached. The maker of the carburetor you mention is the Wheeler-Schebler Carburetor Co., Indianapolis, Ind. They will supply prices and complete data.

2219 **Misses When Under a Load.**

From S. P. Leonard, North Carolina.—I have a 1914 model Ford car that misses on one cylinder and sometimes two when on a stiff grade. It runs fine when on a level road and will idle nicely. When going up a hill it will miss and explode in the muffler. It will sometimes stop unless I get into the low gear. I think the trouble is in the ignition. I have tried batteries but the miss is there just the same. I took out the spark plugs and laid them on the cylinders and cranked the engine slowly with batteries supplying the current. Two plugs sparked good but the others gave but one quick spark and quit. The vibrators work right on but there was no spark at the plugs. The car is equipped with a K-W master vibrator. What puzzles me is why the plugs will fire when in the cylinders and miss when on a grade. The plugs are in good condition. Have a new timer, wires and points on vibrator.

Reply.—If your plugs and ignition be working properly as you say you must look elsewhere for your trouble. The symptoms are those of mixture and valve trouble, particularly as you obtain a firing in the muffler. Generally speaking this is due to a weak mixture, a mixture that burns so slowly that the flame continues after the intake valve has opened and the fresh, incoming charge is ignited. Another cause of backfiring is faulty seating of the valves. The fact that the plugs on the cylinder head gave but a single spark and stopped sparking even with the coil vibrating may have been due to a short or ground of the plug or wire leading to it. If you have extra plugs remove the two which gave trouble and substitute the spare ones. If after doing this and adjusting the carburetor the trouble continues, look the valves over. The firing of the plugs when the car is running on a level road may be explained by the statement that the quantity of mixture taken in by an engine varies greatly with the speed.

Covering Ford Springs.

From Ralph O. Waterman, Vermont.—Cut a piece of rubber blanket, or any pliable waterproof material so it will nearly go around the spring between the frame and the end of the spring. Lace or sew it together, after you have cleaned and oiled the springs thoroughly, and your Ford will ride lots easier, even if you are driving in the mud a great deal.

Adjusting Ford Coil Vibrators.

From Oscar Barnes, Wisconsin.—Everyone realizes the importance of having the vibrators of the Ford spark coil adjusted to the same tension. Here is a method of doing the work easily and quickly. Remove all blisters and knobs with a thin file or a strip of sandpaper. Then select one of the coils as a pattern or model for adjusting the others. Lay the model and one of the others on a table with the vibrator end of each toward the other. Take a match or a toothpick and place one end of it against the vibrating spring of one coil and the other end against the spring of the other coil. Then adjust the coil so that the points start to separate on it at just the same time that the points separate on the coil used as a pattern when you slide the coils slowly toward each other. Repeat this with the remaining coils using the same pattern coil or model. The match or toothpick should rest against the vibrator spring at about the same distance from the end of the spring on each coil.

Ford Valves Made Adjustable.

From D. L. Moore, New York.—Having a Ford on which the valve and push rod clearance was too great, I fixed it in this manner. Removed the valve, and cut threads up beyond the small hole that holds the pin under the spring cup. When replacing valves, this small pin is not used. A valve spring compresser or remover is needed. Put valve back in motor, and screw two nuts of the proper size on valve stem, the thicker the better. Then the valves can be adjusted by raising or lowering the lower nut on the stem and locking with the upper nut which will also hold the spring in place. This provides a means whereby the valves can be adjusted at any time as they wear. The lower nut projects below the end of valve stem, and the push-rod being larger than the hole in nut provides a new surface to work on.

Likes the Trouble Department.

From W. G. Brown, Connecticut.—Enclosed please find my check for two years' subscription to your paper. My father says he has read a number of automobile papers but thinks yours is the best. I have never taken any other but I think yours is pretty good. I have read a number of interesting articles and obtained some valuable information. Had a similar experience to that of one of your readers who burned out his bearings, but in my case it was caused by running a very long distance on the low speed as the roads were in bad shape.

CARE OF THE FORD MAGNETO.

Some Pertinent Facts Explaining Why Trouble Is Experienced and the Remedy.

The general design and principle of the Ford magneto—or magnetic flywheel, as some term it—are merely a practical utilization of an old idea, dating back to the time when magnetism and electricity were beginning to be first understood, or experimented with, by scientists. We must concede that it is a clever utilization, as embodied in the Ford car, for here it is used, not only to provide ignition current for the engine, but also for lighting head lamps, sounding an electric horn, lighting up—momentarily at least—clock and speedometer, and also one's garage on occasions, not to mention its use at night on the road for inspection purposes.

Construction Is Simple.

Originally, Ford users were supposed to use the magneto solely for ignition purposes, but many soon discovered that it would also light headlamps and sound an electric horn; they used it for these purposes, and in consequence were not over-popular

Digitized by Google

with the Ford organization generally. Public opinion, however, eventually proved too strong even for the Ford Company, and they so far conceded matters as to improve the magneto by enlarging and strengthening the magnets and the stator with its coil spools, to provide extra current for headlamps and horn; in fact, electric lamps are now standard fittings.

In itself, the Ford magneto is a very simple thing, and there is practically nothing to get out of order or give trouble, when it is new, or comparatively so, except through accident, ill-usage, or neglect. Nevertheless, there are many little points about it that it is well to understand, to save trouble. Possibly its worst feature is that, only providing an alternating low-tension current, it necessitates the use of low-tension wires, a low-tension distributer or commutator, and four induction coils of the vibrator type. These parts, with a number of terminals—no fewer than twenty-six in all, counting three on each coil unit and one at each plug—give far more trouble than the magneto parts proper, but as they are so well understood by users generally the writer need not refer to them again.

How Magneto Is Made.

The Ford magneto itself consists of two parts. First, there are bolted round the engine flywheel the sixteen permanent magnets which revolve at engine speed; then there is the circular stator, with sixteen coil spools, stationary, and bolted to the lower part of the cylinder casting.

The sixteen permanent magnets have been twice enlarged and strengthened. Originally (1909-10) they were $\frac{9}{16}$-in. on face, from 1911-15 they were $\frac{5}{8}$-in., and now they are $\frac{3}{4}$-in. The coil spools also were altered in size, the original small round ones being now replaced by larger coils, oval in shape.

The sixteen magnets are bolted at their curved or inner ends of the flywheel, while their poles are connected to each other by clamps—like poles, north or south, being connected together all round, and also bolted to the outer periphery of the flywheel.

On the stator the sixteen coil spools are connected to each other all round by soldered copper strips, one end of the wiring being insulated, and attached to a stud terminal at the top which forms the current conductor to the insulated terminal on the outside clamps are separated from the coil spool surfaces by 1/32 of an inch. In revolving quickly at engine speed the magnets, in passing the stationary coil spools, create an alternating low-tension current in the coils, and this is carried from the coils to the current conductor and external terminal before mentioned, the last-named being connected by a wire to the coil box on the dash.

How Troubles Develop.

While new, there is no trouble whatever to be expected with either magnets or coil spools, but after lengthy use, as may be imagined, various faults may develop to hinder a full flow of current and cause engine misfiring. The magnets themselves may weaken, though they do this but rarely within, say, five years.

Never should the owner, except under expert guidance, attach a battery wire to the magneto terminal, for this may demagnetise the magnets. In case the magnets become weak by long usage, or from any other cause, they can be remagnetised very cheaply, or a new set can be purchased. This necessitates, unfortunately, the removal of the whole engine unit from the frame, and the same work is entailed in case of any trouble with the magneto coil spools.

Dirty oil in the crank case may cause trouble. To avoid this drain out the old oil occasionally, then put in a quart or two of kerosene, and run the engine slowly on this for one minute, afterwards letting out the kerosene and filling up with fresh, thin, but good oil.

Trouble is not infrequently caused by dirt and obstructions gathering round the current conductor on the stator, under the magneto contact on the top of the transmission cover. Small pieces of brake band linings, worn from the ends of the fabric, may be a fruitful cause of this kind of trouble. Foreign matter of all kinds, generally in dirty oil, may get on the magneto coil spools, and also on the magnets themselves, and cause defective ignition. The coil spools or bobbins may also "short" within themselves.

Avoid Metal Particles.

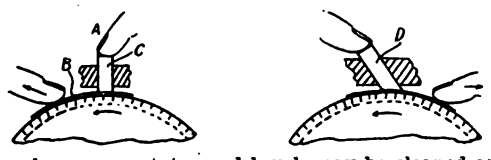
As every motorist knows, wear of all the moving parts of the engine causes minute pieces of metal to become mixed with the oil, but these may be as large as filings or even larger; they may be seen in profusion if the oil be taken from the engine base chamber and strained through linen. These particles are apt to accumulate if fresh engine oil is invariably added without first drawing off the old oil, and for this reason alone it is most important, at regular intervals, to drain the old oil out and flush the engine out with kerosene, as mentioned. In the case of the Ford, the fine filings or miscroscopic chips of metal (if one may so call them), becoming mixed with the oil, are naturally picked up by the magnets and thrown on the cores or faces of the coil spools; they may be seen adhering to both when removed. As the magnets revolve so close to the cores of the spools, the metal particles may cause deterioration of the quality or power of the current.

A nut, cotter pin, washer, or even a wrench dropped accidentally into the transmission case of a Ford, may be picked up by the magnet and cause damage; all tools used inside this case should have a long piece of string attached, so that, if dropped, of the transmission cover. The other end of the coil spool winding is grounded on the stator frame bolted to the engine.

When properly fitted the faces of the magnet they may be recovered.

The spool coil insulation may break and set up a short circuit, or the same result may be caused by the grounded end of the coil wire becoming detached from the stator. Yet, again, trouble may be due to the soldered ends of the copper ribbons between the spools breaking. These mishaps rarely occur, but are always possible after years of hard service.

There is a tendency on the part of some owners to blame the Ford magneto for weak current or misfiring when the real cause may be looked for in the coil box wiring; that is, in the false bottom of the box, or in the induction units or the wiring. Fully one-half the troubles attributed to the magneto are due to dirt or foreign matter deposited by the oil on the magnets or spool coils. Ford repairers often receive cars with the instruction, "Magnets require magnetizing," when all that is needed is a good cleaning and washing out of the engine and transmission with kerosene. Some owners will run a



Digitized by Google

car 10,000 miles or more and never think of removing the dirty oil, charged as it must be with all kinds of foreign matter.

The strength of the magneto can always be tested with a voltmeter. In this case, run the engine on the battery ignition, then try the voltage from the magneto terminal to ground. The reading should be six volts at cranking speed, and as much as thirty volts may be registered as fast engine speed. If the engine will start and run well on the batteries, but stops when switched over to the magneto, it will prove that the magneto is at fault. If it has to be dismantled, care must be taken when removing the magnets to lay them round a board just in the position they occupied round the flywheel, and in reassembling them to put them back as they were originally. Each magnet should be capable of lifting a weight of about four pounds.—J. T. Ward in the Autocar.

Seating Commutator Brushes.

To obtain satisfactory results from the generator or other electrical unit utilizing a commutator and brushes the brushes must bear evenly and uniformly upon the segments of the commutator, else sparking will follow and a burning action be set up on the commutator. This will result in a loss of energy or output of the unit. The accompanying drawings

Illustrating how commutator and brush may be cleaned and shaped by use of sandpaper.

illustrate how brushes may be fitted. That at the left depicts how a vertical type of brush can be fitted to the commutator by placing a piece of fine grade sandpaper B on the commutator, thereby pressing one finger A on the brush and another finger drawing the sandpaper as indicated by the arrows. The sketch at the right illustrates a brush held at an angle, but the direction of movement of the sandpaper is different as is indicated by the arrows.

VALVE TIMING.

Accuracy Absolutely Necessary for Motor Efficiency and Smooth Running.

From William H. Stewart, Jr., Stewart Auto School, New York.—It is hardly conceivable to the average driver why a slight disarrangement of the valve timing should cause loss of power and otherwise upset the proper working of the motor. However, if one studies the working principle of a gasoline engine it is not difficult to comprehend why accuracy in valve timing is necessary.

In the four-cycle type motor the crank shaft makes two revolutions to complete the cycle of operations. The suction and compression stroke is one revolution; the firing and exhaust stroke is the other. The charge of gas is taken into the cylinder by the down stroke of the piston and compressed by the up stroke. Likewise, when the charge is fired the piston is forced outward and on the second up stroke the burned gases are exhausted. In order to admit the new gases to the cylinder the intake valve, timed to open and close at the right instant, is necessary. Likewise an exhaust valve.

Ordinarily, one would think that these valves would open and close at the end of the strokes, but such is not the case. A fixed "lag" and "lead" are given the valves according to the design of the motor. Ordinarily the intake valve is timed to open at a point about 12 degrees past top center and to close at a point about 30 degrees past bottom center. The exhaust valve opens about 40 degrees before bottom center and closes about 10 degrees past top center. Top center is determined when the piston is up; bottom center when it is down. Since there are 360 degrees to a cycle, the flywheel is usually marked in a manner to fix these points of opening and closing.

Motors differ considerably as to valve timing. The size and lift of the valves, cylinder bore, and the revolutions per minute of the motor, together with numerous other factors, determine the valve timing. Take, for instance, the intake valves. When the piston begins to travel down a vacuum is created. At this time the exhaust valve must be closed and the intake valve opened to permit the gases being drawn into the cylinder as the piston travels outward. As the crank pin passes through the arc at bottom center the piston for a time is at a standstill. However, the inrushing gases continue to flow into the cylinder until the piston begins to travel upward on compression. The intake valve should close at a point when the piston would tend to force out the gases already in. The new gases drawn into the cylinder by the suction of the piston attain a certain velocity and for this reason the intake valve is held open as long as possible.

The piston on the upward stroke compresses this charge from atmospheric pressure to that of about sixty-five pounds. As it again reaches top center of compression the spark is timed to ignite the charge which, in burning and expanding, forces the piston outward on the firing stroke. As it travels outward on the firing stroke the pressure exerted is reduced, the effective pressure being exerted on the piston during the early part of the stroke.

The exhaust valve is timed to open before the piston reaches bottom center in order to permit excess pressure to escape before it returns on the up stroke. If this lead were not given to the exhaust valve, under pressure would be exerted on the piston during the scavenging stroke.

Since three of the four strokes are idle the energy consumed in effecting this would cause additional loss of power. As the piston travels upward on the exhaust stroke the burned gases are expelled through the exhaust valve, which is also held open as long as possible to take advantage of the velocity of the gases. In short, the exhaust valve may remain open until the piston begins to travel down on the suction stroke and tend to create a vacuum. At this point the exhaust valve must close and the suction concentrated at the intake valve, which should then open.

Heavy valve springs are used to return the valve to its seat quickly when the point of the cam leaves the roller. One may readily note the order of firing of cylinders by observing the action of either the intake valves or the exhaust valves. If it is 1, 2, 4, 3,

Digitized by Google

No. 1 valve will actuate first, No. 2 next, No. 4 next, and No. 3 last.

In timing a multiple cylinder motor it is necessary only to time the intake and exhaust valve of one cylinder. Cam shafts are constructed so that timing of the other cylinders would be the same as that of the first.

When the flywheel is marked indicating the points of opening and closing of the valves it is an easy matter to determine the top center or bottom center of the piston and then give the necessary lead to the valve. If the flywheel is set in a position where the exhaust valve should open, the timing gear may be turned in position, so that the cam will be about to raise the valve lifter. Likewise, the intake valve may be timed by setting of gear. The design of the cams should take care of the duration of opening of the valve. A slight clearance between the valve stem and the valve lifter is given. This clearance is necessary to allow for the expansion of the metal when heated, otherwise when the motor is hot the valve will become unseated, due to the elongation of the valve stem. Likewise, if too much clearance is permitted at these points the lift of the valves will be lessened and the exact opening and closing points disturbed. This space should be in accordance with instructions of the manufacturers.

If the valves are not timed accurately the motor will not develop its maximum efficiency, or even may not run at all. Reseating occasionally is also necessary. Especially is this true with the exhaust valve, which is subjected to considerable heat and waste products of combustion. The inrush of fresh gases past the intake valve has a tendency to keep it clean, and for this reason this valve does not foul so readily. However, a slight particle of carbon on the valve seat will cause loss of compression, and when the compression is reduced loss of power results.

OBITUARY.

Arthur A. Hill, who has been editor of the Automobile Dealer and Repairer since this publication started in March, 1906, died at his home in this city Thursday, September 13, following an attack of apoplexy.

Mr. Hill was born in Greenwich, Massachusetts, and was in his sixty-fourth year. He at one time owned, controlled and edited The Haverhill Gazette, published at Haverhill, Massachusetts, giving to that publication a degree of influence which it had not previously enjoyed. In 1890 he became managing editor of the American Press Association, of New York City, leaving that organization for the purpose of making a trip to the Klondike gold regions. On his return from the Klondike he purchased an interest in The North Adams Evening Herald. Later on he sold his interest in The Herald, and became editor of The Blacksmith and Wheelwright and The Amateur Sportsman, published by the M. T. Richardson Company. In 1906 he also became editor of the Automobile Dealer and Repairer. He was one of the original members of the New York Press Club.

In his youth he was connected for a time with The Springfield (Massachusetts) Republican, and afterwards connected himself with a big publishing and printing concern in New York, to learn the business. Tiring of this, he went to Ohio, and entered Oberlin College, where he remained long enough to get a smattering of the classics, paying his way by work in the local printing office. Before he was 21 he had become a reporter on The Cincinnati Gazette and a compositor on the Chicago Times, and for a year a reporter and city editor on The Toledo Democrat and Herald.

Mr. Hill was the author of a novel of unusual merit, entitled "What's He to Me?" and published in 1914 by Howard O. Bullard, of New York.

He was a man of pronounced opinions, and a forceful writer upon any topic which interested him. He was especially sympathetic with all economic and welfare problems. He welcomed a condition which should be productive of moderate wealth widely distributed, rather than a concentration of wealth in a few hands. He possessed a rare vein of wit and humor, which fairly sparkled at times in his conversation and writings. He formed and maintained

ARTHUR A. HILL

warm friendships with a large circle of acquaintances.

Mr. Hill's generosity was proverbial. He could seldom resist an appeal for help and many a down-and-out fellow creature has had cause to remember him gratefully.

Leads in Automobiles.

There is one automobile for every twenty-nine inhabitants in the United States, according to figures for last year, made public by the Federal Public Roads Bureau.

Iowa with one car for every eleven persons, led the country in the number of machines registered in proportion to population. California, Nebraska and South Dakota ranked next in order. Arkansas, with one automobile for every 116, is at the foot of the list. The New England States were more uniformly supplied with motor cars than any other section, it was stated.

Missing Numbers—Our Readers are requested to remember that it always gives us pleasure to re-send numbers which have gone astray in the mails.

The Automobile Dealer and Repairer in Australia and New Zealand.

Mr. R. Hill, Matlock House, Devonport, Auckland, New Zealand, is our accredited representative in Australia and New Zealand for obtaining new subscriptions.

ARE MOTOR CARS TO BE DEARER?

Can there be any doubt about it, with the tremendous demand for constructive material of all kinds brought about by the war?

Everything entering into the construction of a motor car is likely to cost the manufacturers more than it did. That being the case, car manufacturers, it would seem, must increase prices, to save themselves.

The man who has been putting off the purchase of a motor car, either under the impression that they might be cheaper, or for some other reason, should wait no longer. If he does, he will undoubtedly have to pay more money for his car.

AN EASY DEATH.

To be instantly killed by collision with a railroad train, while it usually leaves the victim in a more or less mangled condition, may not be as terrible a death as it seems. Some years ago a friend of the writer was riding along in his automobile on a road that ran parallel to the West Shore railroad. At a certain point, the public road veered to the left, over the railroad track. The automobile reached the crossing at precisely the time that the train was coming along, and the train struck it squarely, hurling its occupant fifty feet or more. He was picked up unconscious, and did not regain consciousness for three weeks. He finally fully recovered. The cushions of the automobile in some way saved his life. After he was well he was asked one day what his sensation was when the train struck his automobile. He said that there was no sensation whatever. He did not know he had been hit. He was riding along in his machine, with no prospect of any trouble, and the next thing he knew he found himself in a strange bed, in a strange room, and had no idea how he got there, until the matter was explained to him. He was asked if there was not some sensation of a crush. or a noise, or something of that kind, but he insisted there was no sensation whatever. So if he had never regained consciousness, it would have been an extremely easy death.

GO EASY ON GASOLINE.

The prospect of a shortage in gasoline has moved the Government to recommend that motorists curtail the use of their cars for strictly pleasure purposes as much as possible. Unless this is done, the time may not be far distant when gasoline will be difficult or impossible to obtain at any reasonable price, owing to the great quantities which must be used for war purposes.

Oil wells in old fields are drying up, and new sources of supply have not been found—in this country—and may not be. Until the war closes, foreign fields cannot be depended upon to help out very much.

Many motorists for their own convenience are economizing in gasoline, especially Sundays and holidays, when the roads are so crowded with cars as to make motoring more than ordinarily dangerous and far less pleasurable than on week days.

PUSHING SALES OF AUTOMOBILES.

With the price of wheat guaranteed to the farmer at $2.20 a bushel and other farm products selling, many of them, at a corresponding increase over prices which prevailed before the war, there would seem to be a great opportunity for pushing the sale of automobiles. tractors, trucks, etc., in all agricultural communities.

We may be sure that manufacturers will not neglect the chances presented of increasing their sales among a class of people who have in the past been large purchasers of motor cars.

Manufacturers of accessories of all kinds should prosper with the increased sale of cars to farmers, as they usually buy a low priced car on which many devices can be used to advantage.

A WORD ABOUT TROUBLE.

We hope none of our readers who may be in need of information with respect to difficulties connected with their cars, will hesitate to communicate with us. We stand ready to serve our subscribers at all times, to the best of our ability.

We would ask, though, that all questions with respect to troubles be made as specific as possible. Sometimes the omission of an essential detail in an inquiry makes it difficult for our experts to answer with such precision as is desirable. Give us the facts concisely, and without too much elaboration, and our task in preparing a proper reply will be made easier, and the information we are able to supply will be all the more helpful.

LESSONS FOR DRIVERS

Carelessness and Ignorance Responsible for Most Accidents.

An appalling number of absolutely inexcusable accidents, involving heavy loss of life, have been reported this summer. We refer to collisions between trains and automobiles at railroad crossings. We call an accident of this sort inexcusable because its avoidance only requires the use of one's eyes and ears. Where the track is invisible, a delay of two or three minutes at the most, while the driver alights from his car for a careful inspection, is all that is necessary. Usually, simply slowing down before a crossing is reached is sufficient.

Skidding has been a fruitful cause of accidents this summer.

Two Killed When Train Hits Auto.—A man was instantly killed and his wife seriously injured, when the auto in which they were riding was struck by a mail train near Gresham, Oregon. A granddaughter of eighteen was at the wheel. It is believed that when she saw the train coming she became confused and lost her presence of mind, permitting the car to reach the crossing.

Five Dead from Collision with a Train.—A baby's shoe on the cow-catcher of a locomotive of a Big Four line train at Paris, Illinois, revealed the fact of a serious collision with an automobile, in which five persons lost their lives. Apparently in this case the driver was paying no attention whatever, as the engineer stated that the driver drove his machine on to the track a few feet ahead of the train, and was leaning out on one side of the car, talking to one of the children. The driver and owner of the car and four children were killed.

Three Deaths from Collision of Train with Automobile.—A truck farmer, his wife, and little son, were killed when their auto truck was struck by a Union Pacific train at Topeka, Kan. The woman was driving, and the car stalled on the track. It is believed that the accident was caused by a desire on the part of the driver to save time by getting ahead of the train.

Passenger Train Hits Automobile.—In Dorchester, Mass., three members of one family lost their lives when their automobile was struck by a passenger train on the New York, New Haven, and Hartford line. The driver saw the train coming, but not soon enough to stop before reaching the crossing, although it was said he jammed on the brake, and his machine skidded.

An Erie Train Strikes an Automobile.—A woman of seventy was killed instantly, and her daughter and son-in-law were injured, when their automobile was struck by the Chicago Limited, on the Erie, at Ackerman's Crossing, N. J. Their automobile stalled on the track, and the occupants had ample time to get out, but apparently paid no attention to the approaching train.

One Man Killed and Two Others Badly Injured.—The failure of a driver of an automobile at Springdale, Pennsylvania, to notice the approach of a freight train recently resulted in his death and the serious injury of two others who were riding with him.

Dancing Pumps Cause Motor Car Wreck.—A pair of dancing pumps, according to the Omaha News, caused a collision between an automobile and a street car recently, by which four persons were seriously injured. The woman driving at the time of the accident explained that she saw the street car in time to stop, but could not apply the brake properly with the light slippers she was wearing in place of the high, strong shoes she usually wore.

Crushed by an Express Train.—A chauffeur for a New York contractor drove his automobile on to a West Shore railroad crossing at Dumont, New Jersey, just in time to be struck by an express train. Both the chauffeur and the contractor were instantly killed, and their bodies horribly mangled. The automobile was twisted and bent into scrap iron. The fiancee of the contractor was standing on the porch of her house and witnessed the accident.

Two People Killed by a Train.—Near Milton, New Hampshire, the manager of the Hotel Rochester and his fiancee were both killed, and the engine and a mail car derailed. The couple were to have been married in a week.

Too Much Speed at a Curve.—One man had his back broken, and several others were seriously injured when a car in which they were riding broke down a guard-rail over a creek near Danville, Pennsylvania, and plunged 26 feet to the bed of the creek. There was a sharp curve at the point where the accident occurred, and the driver of the car did not slow up in time. Serious accidents are all the time happening at sharp curves, because of too much speed.

Fatal Collision with a Traction Train.—When an inexperienced driver near Ampers Station, California, pulled the wrong lever of the car, and shot it into a swiftly moving train recently, two people were killed—a man and a woman. The driver, a woman, escaped with a few scratches.

Train Smashes Automobile.—Three persons were killed and one injured seriously when an automobile near South Sudbury, Massachusetts, was struck by a New York, New Haven and Hartford train. The driver applied his brakes when he saw the train, but the machine skidded.

He Didn't Notice It.—A woman of eighty-five was instantly killed, and three other people seriously injured when an automobile was struck by a passenger train near Carthage, New York. The driver did not look nor listen, and neither saw nor heard anything, he said.

They Didn't Hear the Whistle.—At Monocacy, Pennsylvania, two persons were killed and two others seriously injured when the automobile in which they were riding was struck by a Pennsylvania express train. The engineer of the train blew his whistle, but none of the party heard it.

Reckless Driving.—A reckless driver near Tarrytown, New York, during Flag Day exercises, drove into a crowd of school children and others, killing one man and injuring several other persons. The driver refused to stop, but was pursued, caught, and landed safely in jail.

Result of Recklessness.—Near Lansdale, Pa., a young man sixteen years old was driving a big car at fifty miles an hour on a stretch of macadam road when he undertook to pass a horse and buggy. This he did, but in trying to regain the road he slid to the opposite side, when the car twice overturned and landed right side up pretty well demolished, and the young man beneath it, where he bled to death.

LEGAL RESPONSIBILITY FOR DAMAGE AS BETWEEN MANUFACTURER AND DEALER.

An Automobile Case.

(Copyright, April, 1916, by Elton J. Buckley.)

The law is becoming more and more firmly settled that a manufacturer who makes a machine, or a store appliance, or a food product, and sells it to a dealer to sell again, is liable to any purchaser who is injured by reason of some defect in its construction or manufacture. It used to be a theory—and there are some cases to support it—that where a manufacturer made something and sold it to a dealer, he was responsible only to the dealer, for the dealer was the only person with whom he had any contractual relations. If the product, whatever it was, was sold by the dealer to a consumer, and in the hands of the latter it went wrong, showing defective manufacture or construction, the consumer must look to the dealer for redress because it was the dealer with whom the consumer dealt.

The courts soon awoke to the fact that this was a gross injustice because it made a dealer responsible for something over which he had no possible control, and which he could not even know about, viz., the construction and composition of another man's product. The courts then began to decide that a manufacturer—who alone can know whether his product is good or not—should be held responsible for defective construction or composition in the hands of the ultimate consumer, no matter how many hands it had to pass through before it reached the ultimate consumer. This is of course as it should be, and nothing short of it would be fair.

The clearest decision on this point of law which I have ever seen has just been handed down by the New York Court of Appeals in a case involving an automobile. The manufacturer of the car sold it to a dealer, who sold it to a consumer. While the consumer was using it one of the wheels broke in a way that revealed defective construction, and some damage was done. The owner of the car did not bother with the dealer but entered suit at once against the manufacturer. The lower court gave him a verdict, the manufacturer appealed, and the verdict was affirmed by the Court of Appeals. In its decision the court in a very few words summed up the responsibility of the manufacturer to ultimate consumers, as the weight of the law at present holds it. The following extracts from the decision are clear. I think I should say that the manufacturer defended first on the ground that he was responsible only to the dealer, and second on the ground that he bought the wheel from another manufacturer and therefore was not responsible anyway:

> The manufacturer of a finished product of machinery which is to be used without new tests and which in the nature of things is reasonably certain to place life and limb in peril, is under duty to make it carefully, and for a neglect to do so is liable to the owner who purchased it of a retail dealer. Such liability is not relieved by the fact that the manufacturer obtained the defective part of a reputable maker if a reasonable inspection would have disclosed the defect.
>
> From this survey of the decisions there thus emerges a definition of the duty of a manufacturer which enables us to measure this defendant's liability. Beyond all question the nature of an automobile gives warning of probable danger if its construction is defective. This automobile was designed to go 50 miles an hour. Unless the wheels were sound and strong, injury was almost certain. It was as much a thing of danger as a defective engine for a railroad. The defendant knew the danger. It knew also that the car would be used by persons other than the buyer. This was apparent from its size; there were seats for three persons. It was apparent also from the fact that the buyer was a dealer in cars, who bought to retail. The maker of this car supplied it for the use of purchasers from the dealer. The dealer was indeed the one person of whom it might be said with some approach to certainty that by him the car would not be used. Yet the defendant would have us say that he was the one person whom it was under a legal duty to protect. The law does not lead us to so inconsequent a conclusion.
>
> We think the defendant was not absolved from a duty of inspection because it bought the wheels from a reputable manufacturer. It was not merely a dealer in automobiles; it was a manufacturer of automobiles; it was responsible for the finished product; it was not at liberty to put the finished product on the market without subjecting the component parts to ordinary and simple tests.

This seems unanswerable, but one of the judges disagreed with it and filed a dissenting opinion on the ground that the manufacturer should not be held responsible to anybody but his immediate buyer.

The above extracts represent what would be considered the weight of the law, not only in the case of an automobile, but in the case of everything else that is sold by the manufacturer to dealers to be sold again. If they go wrong the dealer cannot be held responsible unless he has made the transaction his own by giving his own individual guarantee. I will discuss that presently. There are several companion cases on record in which suit was begun against the dealer instead of the manufacturer, and in which the court held that the responsibility was not the dealer's, as he could know no more about the construction of the article than the consumer. These cases as well as the others of the type of the above automobile case, point directly back to the manufacturer, as they should do. They fix upon him the responsibility of warranting, either expressly or by implication, that his article is as it should be; that the wheels on his automobile are good enough to stand the strain; that the colors in his fabric will not fade unduly; that the steel in his farm implement are without flaw which inspection could discover; that the prepared beef in his tin is free from disease germs, and so on and so on.

But the whole situation is changed if the dealer gives a guarantee of his own. In that case he is just as responsible as the manufacturer and an injured consumer can sue him under his own guarantee. Many dealers are foolish enough to do this, but they always take a risk. No dealer should guarantee anything that he does not know absolutely about; his representation should be "the manufacturer's guarantee is so and so," and in all his literature and his advertising he should be particular to say "guaranteed by the manufacturer," never "we guarantee."

Highways Must Relieve Railroads.

With the railroads of the country already taxed to the limit, so that frequent embargoes against additional freight are necessary, other means of transportation must be utilized and developed to the utmost. Secretary Redfield, of the Department of Commerce, in a recent public statement, pointed out the patriotic duty of communities located on navigable inland waterways to divert as much shipping as possible to such waterways, as otherwise the coming demands of the government upon the railroads will inevitably produce a shipping situation from which the country will suffer.

Fuller use of the highway system of the nation, in addition to the waterways, offers the only relief. With record-breaking farm products to be moved

Digitized by Google

this fall and greatly increased output by mills and factories, the highways will be called upon to carry a great deal more of the commerce of the nation than ever before. Not only will the volume of hauling to market over short roads be much heavier, but there is certain to be a big development in the use of motor trucks for local distribution and for freighting over through routes for distances of one hundred miles and more.

"It must be evident," says R. D. Chapin, chairman of the Good Roads Committee of the National Automobile Chamber of Commerce, "that the highways are a greater economic necessity in time of war than in normal conditions of peace. It would be foolish to limit road construction and maintenance any more than is absolutely necessary. If we are to get the crops to market it is of vital importance that the roads be maintained in usable condition. It will be the worst kind of economy to neglect them just at a time when they are called upon to carry the heaviest burden of traffic to meet the urgent needs of the country. Unless so maintained they will deteriorate rapidly. It is even more important now than heretofore that highway appropriations be properly spent and that road work go on as usual."

A Tire Repair School.

One of the natural results of the tremendous increase in the number of motor cars and their operation, is the insistent demand for expert vulcanizers to carry on the tire repair business which has followed in the motor car's wake. Among the tire repair schools that has set about to relieve this condition by training men in the art of repairing tires, with a remarkable degree of success, is the one established about eighteen months ago by the Goodyear Tire & Rubber Company at Akron, Ohio. It is an interesting group of men who gather in the class-room of this school on beginners' day, seeking expert instruction from D. R. Cain, dean of the school. In every class representatives from every section of the country present themselves—dealers, men who want some good repair experience before launching out into the business, and often experienced repairmen.

"We are furnishing a complete practical course," states Mr. Cain. "Beginning with fundamentals, we demonstrate every step in scientific repairing. Occasionally we get men with no idea whatever of how a tire is made—and some who have never examined a tire, but before these men leave our school they are master vulcanizers, competent to undertake any kind of repair, from a simple puncture to a retread.

"We start them all at the same point in the practical work—cutting down sections of tires. After the student becomes skillful in this, he is instructed in building them up. Then we take him through all the various divisions of the business.

"Individual instruction is given to each man. After two weeks' experience we require all students to submit to an examination, and issue the Goodyear Master Vulcanizer's diploma to those who pass. That almost without exception the men pass with high marks is indicative of the thoroughness of our instruction. Because of the great demand for admission, our classes are usually filled up weeks in advance.

"We use the working equipment of the average tire repair shop, and only methods that can be employed by any tire repairman with a modest capital. When you consider that nearly 4,000,000 cars are now in service offering opportunities for repairs on 20,000,000 tires, you may realize why so many men, desiring to become competent repairmen, are entering our repair school."

To Drill Oblique Holes in Iron.

To drill oblique holes in say, a hand rail A, with an ordinary drilling machine, the holes B, being intended to receive the railings C, as shown at Fig. 1, a block of the proper inclination or pitch, and provided with a hole or slot to receive the arm of the clamp E, must be prepared. A piece of elm will be suitable wood for the purpose. If the drilling machine is provided with a table, the block must be cut and secured to this table. But if the machine has a vise, as shown in Fig. 2, the block can be held by this. Next prepare a piece of iron F, one end of which should be vertical when fixed to the bar A, with the clamp A, as shown. This piece of iron will keep the drill in a vertical position; but the drill will have to cut unevenly, and as a precaution care should be taken to provide a slow feed.

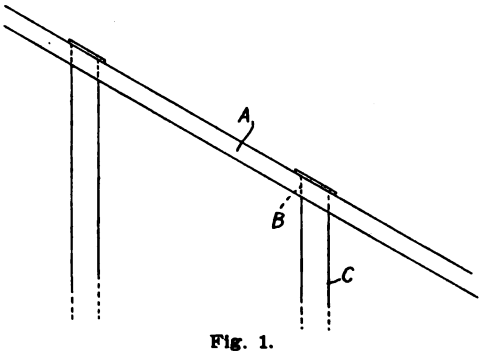

Fig. 1.

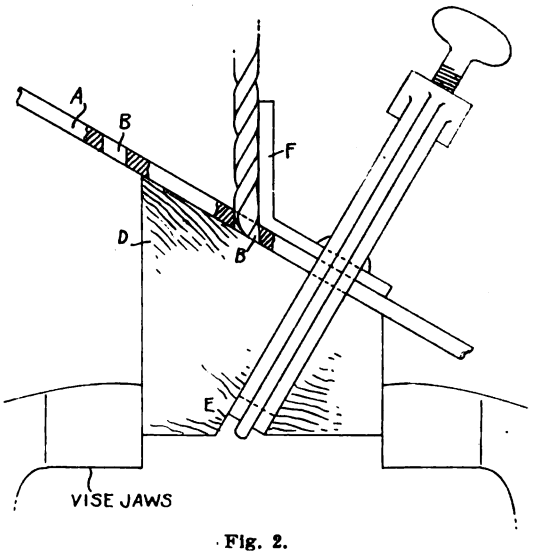

Fig. 2.

Illustrating how holes may be drilled in slanting objects.

Spark plug porcelains crack from a variety of causes. A chance blow from a wrench while tightening, pulling too hard on the ignition wire, dropping the plug or a defect in manufacture are frequent causes. But the usual trouble is from screwing them too hard into the cylinder. As the plug heats up and expands it cracks the porcelain.

WHAT DEALERS WANT.

They Suggest How Manufacturers Might Better Co-operate for Better Business.

Our contemporary, The Horseless Age, publishes a consensus of the opinions of automobile and accessory dealers as to what manufacturers should do to further the sale of their products. It will be found unusually good reading for the manufacturers and will find a responsive echo among dealers everywhere who are not represented in the symposium:

Want More Co-operation.

The manufacturers and dealers should get together on a closer co-operative basis, price maintenance should be strictly insisted upon, a longer profit should be granted the dealer and the manufacturers and jobbers should conduct an educational campaign for the benefit of the dealer who does not conduct his business on a business basis. They should apply to the automobile business the same good principles that make success in other lines.—Davenport, Iowa.

We cannot compete with the mail order houses and give service which they do not give. The manufacturers should help us organize into some form of an association for the purpose of perfecting and promoting service to the tradesmen. Such an organization could keep its members informed as to changes in carburetor design, adjustment, weak points in different makes of cars as well as good and bad credits, etc.—Lyons, Michigan.

Co-operation between the manufacturer and the dealer would result in greater sales. A closer union of working and exchanging of ideas and suggestions or improvements on an article is needed. For example, I might do a certain line of advertising that would sell my goods to the best advantage and a dealer in another territory handling the same line would not obtain the same results with his advertising. An exchange of ideas would be beneficial in cases like this.—Hoagland, Indiana.

Ask for Better Service.

If the manufacturers would appoint agents who are willing to do what is right in giving service and maintaining prices it wouldn't be half as hard to do business as it is now. But as a rule they are offering service which they will not live up to and when an agent who in earnest offers a certain service the prospective buyer has his doubts. Some manufacturers will give you all kinds of help by sending experts and demonstrators, but when the real trouble commences later in the season you don't hear a thing from them—Garfield, Minnesota.

I think that the manufacturers, generally, would be better off if they would give more attention to service than to sales helps. Anybody can sell goods where a reputation for service is established.—Oelwein, Iowa.

Car manufacturers are not particular enough in regard to small details, cars come through unfinished and to a great extent out of adjustment. We feel that a little time spent on cars before leaving the factory would be better for dealer and consumer. Factory branches allow so much for old cars, that should the dealer try to compete for this business, his balance on the ledger would show in red figures. Manufacturers of cars and equipment should make it their business to know what the consumer should pay for their product.—Boston, Massachusetts.

Most of our prospects have an old car to trade, and as the city dealers get about 10 per cent. more commission than the country dealer, it gives him about that much advantage, with the result that the former gets the sale.—Medicine Lodge, Kansas.

The manufacturers could improve conditions if they would give a more liberal commission and at the same time put more restrictions on the sale of the goods they produce. I find that it is not the price so much that sells the goods as it is the quality. Good goods will sell and the dealer can make more by having a longer commission, if the manufacturers will stand back of the goods they put out to the dealer, so as not to encourage price cutting by some little fellow who is just starting out and who does not know what it costs to run a business. As a result of this the good dealer is hurt, as there is always some one else to start and lose money in the same way. Under these conditions the old dealer has to cut prices to stay in business.—Davenport, Iowa.

Manufacturers should try to find some solution for the catalogue or mail order house low price competition. It is rather hard to maintain standard prices when customers quote catalogue prices to the dealer in the smaller towns.—Peterson, Iowa.

Sell the dealer direct at a lower price than the jobbing houses. Material can be bought in New York for 50 per cent. of the local jobber's price. Why not standardize the prices and eliminate the discount.—Madison Lake, Minnesota.

For More Local Advertising.

We believe that the manufacturer should do more local advertising. When you see an advertisement in the local paper it brings home the idea that you can see the car or accessory in your own town. National advertising may be impressive, but when the reader knows that the article described can be found at a local dealer's store this impression may be more lasting, and any desire to see the article can be easily satisfied.—Sioux City, Iowa, and Leader, Minnesota.

Give us good cuts of articles, showing sectional and other views for our catalogue work.—Memphis, Michigan.

A little more co-operation in the service department, and I would suggest that they use more advertising and also help their agents by mailing a stock form letter to all live prospects that their agents may suggest.—Westpoint, Indiana.

The manufacturers could help the dealer by advertising locally as well as nationally. Many people of the country read weekly newspapers as well as magazines. Some never read the latter. Advertising one price only and not changing the styles so often also would be a great advantage to the dealer. Naturally prices are increased more or less with every change in model. The constant changing of models adds to the expense of the manufacturer and in the end comes down to the dealer. We are all out for profit and the appearance of an article determines to a great extent whether or not it is a profit getter. We dealers should insist upon quick sales and small profits, and the strict maintenance of prices.—Carrollton, Kentucky.

More Prompt Deliveries.

The manufacturer should ship repair parts with more dispatch than he does now. He should see to it that the parts are sent via express company that

Digitized by Google

has an office in the town where the dealer is located. For instance, in Fort Madison, we have Adams and Wells-Fargo, but most of the time the manufacturers ignore our instructions and ship by American which means that it takes from three to five days longer for the material to reach us. Every day I see tires and auto supplies destined for Burlington and Keokuk shipped into Fort Madison through Wells-Fargo to be transferred the next day to Adams, which covers those cities. Through this arrangement valuable time is lost. When it comes to service, the manufacturer should certainly look to his shipping department, for there should be a service to dealers just as much as a service to the car owners; they are dependent upon each other.—Fort Madison, Iowa.

The manufacturers should be able to furnish a car at the time that the agent has the best opportunity to sell. They insist on our taking cars when we don't want them and when we do want them they are not to be had. Nothing discourages a dealer more than to sell a car and then find that he can't deliver it. After the customer has waited and waited until he is worn out, an agent for a different car comes along, takes the customer to the city and drives a car home the next day.—Greensburg, Indiana.

To my mind the ways in which a manufacturer can help sales are: (1) A well arranged systematic advertising campaign; (2) Bring out cars and body styles in time without excessive delays; (3) Give prompt and efficient service, and (4) Build an honest and conservative car for a fair list price.—Worcester, Massachusetts.

The manufacturers might have sufficient cars on hand when they announce a new model to be able to make deliveries at once. At present they announce a new model, and then it is two or three months before we dealers in the West get decent deliveries, and you can readily see that this cuts our selling down to ten or nine months. Still they say, "keep up your winter sales and repair business," and don't take into consideration that in order to sell cars we must have them on hand. I think that they should not announce a new model until they have sufficient cars on hand to take proper care of their agents. This is a very vital point with us dealers.—Wilson, Kansas.

Help of Experts.

If a manufacturer should send a real salesman to instruct our men we think it would be a big help. By real salesman, we mean a man who has had actual experience selling motor cars and has made good. There are too many factory representatives who evidently got their jobs by a pull or because of lack of men, and all that they are good for is to make a bill of expenses to be added to selling cost, which is really waste.—Waterville, Maine.

Have expert salesmen make regular visits to the dealers and instruct the local salesmen and car owners in the features and operation of the car they represent. Letters and pamphlets do not do much good, as few people give them serious consideration. An expert factory representative could help local salesmen to close deals that otherwise would be lost. —Brazil, Indiana.

Selling conditions would be improved if the manufacturer would refrain from placing too many agencies for his product in small towns where his goods are unknown and sales are few. Some dealers will stock up with a line and push it only to find that other dealers in his town are handling the same articles. The result is that all the dealers lose interest in the line. Overloading is another bad practice with some manufacturers. A marked improvement could be made if the factory would send one of its road men to dealers who find themselves in this position and have that man help in pushing the items among the local prospects. I find that people are sometimes more convinced with the selling talks of a stranger than with the efforts of the local merchant, provided a little tact is used.—Coleraine, Minnesota.

More Circulars Needed.

Manufacturers should send out letters and circulars with the dealers' imprint at least every three months. These letters should be written for local consumption. I find this a great help. Serial form letters have been very prominent factors in doubling my sales during the past year.—Fennville, Mich.

Better business might be developed if the manufacturers changed their window display material more frequently or arranged for an exchange of this material between dealers every month or so.—Russelville, Indiana.

The manufacturer should produce literature describing his product in such a manner that it would be really understood by the ordinary prospect.—Losantville, Indiana.

Catalogues and prices are distributed too freely among people not in the business.—Webster City, Iowa.

I should think that to furnish special "write-ups" for circular letters to prospects treating on their product, or, better still, supply these letters to dealers would give the dealer great help. Most of us are busy and find little time to properly construct such letters, and may not have the best information to draw from.—Portland, Maine.

Other Complaints.

Last year a number of manufacturers realized a net profit per car in excess of the retailers' net profit. This should not be so. Manufacturers in general, because of the volume, usually net a profit less per unit of manufacture than the retailer realizes. No assistance or suggestions are given as regards the arrangement of window displays, salesmen, etc. The average manufacturer's salesman works under the direction of a branch, usually on salary and commission basis, and he is keen only to load the dealer with cars, the latter to dispose of them as best he can. The direct mail advertising done by manufacturers is helpful when supplemented by periodical letters from the dealers who can instill some local color to the advertising. National advertising not connected by local newspaper or direct mail advertising does not materially assist in local sales. The combination of both is good. The manufacturer does not insist on price maintenance and has not protected the dealers on territory restrictions.

We believe that one step that might be taken by the manufacturers to improve price and territory restriction conditions would be to confine their sales efforts to men or companies engaged principally in the automobile business. In their effort to push their lines in territories already covered by their competitors the manufacturers will place agencies with every blacksmith, hardware or drug store that

Digitized by Google

will handle them. The result is that these stores dump automobile accessories on the market at cut prices in order that they can get a quick return of their money.—Lyons, Michigan.

The manufacturers should study the different localities and give the help necessary for the needs of the various sections. They should not try to overload the dealer. They should help with local advertising and should see to it that all minor troubles in their product are rectified before goods are shipped to the dealer.—Haskins, Iowa.

Manufacturers could assist us in selling their goods by insisting that the dealer get a reasonable margin of profit. In connection with the maintenance of price, we believe that the manufacturers should even go as far as to take their goods from the dealers who do not sell at the list price. At least, they should not sell them any more goods when they know that prices are not being maintained.—Berlin, Iowa.

DEMONSTRATIONS VS. SALES.

How a Truck Salesman Failed to Get the Order and the Dealer Closed the Sale.

BY CHARLES L. FUNNELL.

Not long ago an up-state New York truck dealer woke up to the fact that the largest grocery in his town was using six horse-drawn wagons for delivery work. The dealer sent his salesman around to the store manager with a three-quarter ton truck to make a demonstration. The manager was taken up a few hills, and told about the gasoline used per week, operating costs, etc., but somehow he was not impressed.

A few days later the dealer went to see the store manager.

"What's the matter with the truck idea?" he inquired. "With our truck you can save time and money and cut down on your help."

"Your demonstrator didn't tell me anything about that," explained the store manager. "He kept saying that your truck was the best made and I didn't dispute it for a minute. But our horse deliveries get the goods to the customers all right. Why should we change?"

"I'll show you. Tomorrow morning you let me bring that truck around with a box body on it that will hold a string of those order baskets of yours. Then give me a delivery man and time me on any old route you have."

The grocer was agreeable. He couldn't lose, so the following morning the truck was backed up to the store to receive its load of routed orders. Promptly at ten o'clock they started out on a route that took the horses two and a half hours to complete. The country was hilly, and only a small part of it could be traveled by horses at more than a walk. The truck took most of the grades on second, and succeeded in cutting the running time in half without breaking an egg or spilling any kerosene on the potatoes.

Just to show that it was no accident the garage owner insisted on taking another route, beating its standard horse time by an even better margin than at first. The test resulted in the sale of one truck at once, and a second a month later.

The secret lay in showing the grocer just where the machine fitted in his every day business. It cut his delivery time in half and made possible the delivery of rush orders to accommodate customers. As a three-quarter ton truck, the machine had no interest for him, but as a modern, economical delivery system it proved to be an improvement he could not afford to be without.

The salesman profited by his lesson, and later he sold the ice man and the milkman on the basis of increasing the radius of delivery and in less time than required by the horses. The incident illustrates the difference between order taking and salesmanship.

The Magic Touch of the Wheel.

From C. L. Funnell, New York.—Many a dealer has located a prospect with plenty of money, demonstrated successfully, and then failed to close a sale at the last minute for no apparent reason. Perhaps the possible buyer even expressed pleasure in the performance of the car, and yet failed at the end to make up his mind to part with the necessary cash.

"Closing the sale," remarked a successful garage man the other day, "is not merely half of the job. It is more nearly seven-eighths of the work. Unless you actually make the sale you must charge your time to advertising, and that is the head under which you must also put the cost of gas, oil and depreciation on the demonstrating car. Of course it is an excellent thing to have an almost-owner going about telling friends what a nice ride he had in your machine, but it does not pay the freight.

"The big trick is to get the signature on the contract. Anyone can stir up interest on the part of the prospect. Our plan is to take a man out on a good straight road and let him get behind the wheel himself. If he has never driven before, so much the better. Work his clutch and gears for him, and help him a little with the steering, all the while explaining to him how simple it really is to drive a modern car. After he has steered a bit himself, and perhaps passed a few acquaintances, he begins to think of the car as a possible possession.

"When you do all the driving he feels that he is riding with you and looking at a piece of machinery that you have to sell. It's different when he sees the road sliding in under the fenders and knows that he is guiding the wheels himself. It gives him a mental picture of the long afternoons and evenings of fun ahead of him, and that mental picture is worth more than hours of talk on wrist-pin lubrication and factory methods. When we get a man pretty nearly ready to close we shut up and let the magic touch of the wheel do the rest. It nearly always works."

SOLVES ELECTRICAL PROBLEMS.

Official Auto Wiring Guide Should Be in Hands of Every Repairman.

The increasing use of electric lighting and motor starting as well as the pronounced tendency towards use of the battery system of ignition on pleasure automobiles has complicated matters for the repairman and garageman to say nothing of the owner. The time was when the repairman could handle any electrical equipment because of his practical experience and acquaintance with the devices, but this condition no longer obtains for the simple reason there are dozens and dozens of different types of motor starters and generators, to say nothing of the vari-

Digitized by Google

ous wiring methods. It is, therefore, impossible for any one to commit the multitude of details to memory. Because of this one must consult the wiring diagram of the maker of the system. These diagrams are essential when trouble is experienced or when an old wire is to be replaced with new.

It would not be practical for the repairman to attempt to collect the various diagrams needed in his business as it would take months and be very costly. Then again he would have no assurance that the charts would be correct. All of this trouble has been avoided by the efforts of the International Motor Institute, whose corps of electrical experts have gathered and incorporated in a very comprehensive book diagrams for every system and car manufactured, including many makes now discontinued. There are over 500 pages and approximately as many guaranteed diagrams, and the charts are arranged in the form of blue prints which are very easily read. In addition the brochure gives complete information for the care, repair and maintenance of storage batteries. The book is well bound and is endorsed by leading authorities in the automobile industry. It is valuable if for no other reason than it saves an expensive repair bill for the customer when his electrical system develops a fault.

Care of the Motor Top.

Probably more harm is done to the tops of motor cars by careless folding than in any other way. It is well to dust off the top before folding, for dust between the folds tends to wear away the fabric when the car is in motion. Care should be taken that there are no sharp bends or creases in the top when it is folded.

It is important that the top bows be strapped tightly together, so that there will be no motion or chance for wear between the parts of the top. After the top has been folded for some time, it will be found that the straps have stretched and they should be tightened.

When the top lining has become faded and discolored, it can be blackened by the use of a can of Johnson's "Black-Lac."

If the celluloid windows are worn or scratched, they can be made more transparent by varnishing the rubbed surfaces with a thin coating of transparent varnish. A good varnish for this purpose can be made by dissolving a quantity of transparent celluloid in acetone, making the solution very thin and applying more than one coat, if needed.

To patch a celluloid window, moisten the surfaces with acetone and press together, holding until dry. This will hold securely and be just as transparent as before.

Good Advice Advanced.

With tires one of the largest items of expense the owners must meet, it seems but natural that the tire should receive more than ordinary care and attention. Especially during touring time they will require weekly inspection. If any small cuts less than three-quarters of an inch long are discovered in the tread they should be plugged with plastic rubber. If the cuts are deeper and longer than three-quarters of an inch it is advisable and will be found economical to have them vulcanized. It is not the tread cut itself which is so dangerous as the trouble which may come because of the cut. A tread cut allows water and dirt to enter and the dirt usually forms small lumps, which work their way deeper and deeper into the rubber, finally reaching the fabric. If the fabric should begin to rot at one point that spot becomes weak, and a slight bruise may cause a blowout. A weekly inspection of the tires, with a view of repairing all tread cuts, will result in more tire mileage. The cost of plugging or vulcanizing is not usually one-third that of the cost of the lost tire service.

Rocking Fifth Wheel for Trailer.

The illustrations show how easily a rocking fifth wheel can be made from an ordinary fifth wheel of a wagon, so that a wagon can be used as a trailer attached to an automobile. Fig. 1 shows a side view of the device and how it is attached to the bottom of the wagon and chassis frame. The upper circular part of the fifth wheel A, is bolted to three cross bars B, which are as long as the wagon body is

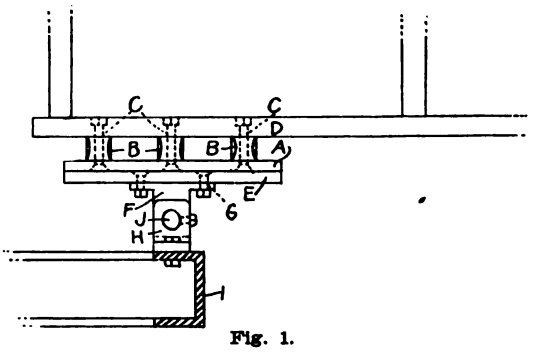

Fig. 1.

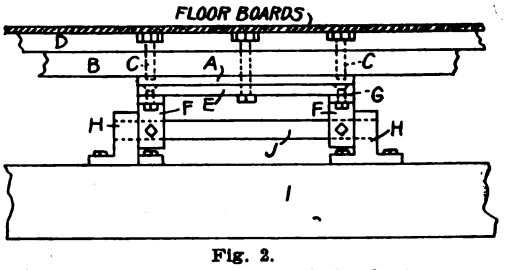

Fig. 2.
Showing application of rocking fifth wheel to wagon.

wide. The bolts C, extend up through the bottom cross bars D, of the wagon as shown clearly in Fig. 2, which is a rear view. The lower circular portion of the fifth wheel E, has two bearings F, bolted on each side, one end of bolt C, and G, being counter sunk in both circular portions of the fifth wheel. There are also two bearings H, of the same size as F, bolted to the rear of the chassis frame I. The bar or shaft J, placed through the four bearings gives a rocking movement to the entire fifth wheel. Bearing F, has a machine bolt to hold the shaft or bar from working out of the bearings H.

Do not fasten chains too tightly nor to a spoke. Many a tire has been ruined by disregarding this advice. If a chain can creep it will wear the tire evenly. If it is fastened so that it cannot creep the cross links wear in one place and the shoe is damaged.

If at any time you open the switch and the engine continues to run it is due to glowing carbon or overheated engine. Close throttle, put gears in low speed, apply foot brake gently, and let it clutch suddenly. This will stall motor.

A MARVELLOUS INDUSTRY.

And the Importance It Bears to the Welfare of the Country.

The following article by Alfred Reeves, general manager of the National Automobile Chamber of Commerce, was written for the information and use of the members, and some of the members of that organization might read it with a good deal of profit, but it is good general reading as well, giving as it does many important facts concerning a gigantic industry and the most useful vehicle ever used by man.

"We are all engaged in one of the greatest and most useful industries in the country. We are proud of the progress it has made, of its strength and stability and of the high character of the men engaged in it. Let us take it seriously and unite our efforts to convey this feeling to every one else.

"Don't call it a pleasure car—call it passenger car or automobile. Don't dwell on luxury—keep utility in the public mind. Don't advertise useless stunts —dwell on economy of consumption, saving of time of busy men, low upkeep; encourage fuel saving by contests and in other ways. Don't exaggerate sales, profits, production, etc.—be moderate, or say nothing along these lines. Don't send out extravagant stories about the vast sums of money spent for cars, equipment, supplies and touring. Don't dwell on speed and power—talk about durability, safety and convenience of use. Don't feel obliged to get a free advertisement into every publicity article—do some constructive work for the industry as a whole: the papers and the public will like it better. Don't take too seriously the talk about failure of the supply of gasoline and possible curtailment of use of passenger cars.

"Gasoline should be economized and waste avoided. However, processes for extraction of increased percentages of gasoline from crude oil are being put into extensive operation. Kerosene can be used successfully if necessary and there are a number of kerosene carburetors on the market. Government reports show almost unlimited deposits of oil-bearing shale in western states from which large quantities of gasoline can be extracted. Many oil wells in Mexico are still capped. Alcohol can be used as a gasoline substitute or in combination with it. Any farmer can distill alcohol from waste products at small expense if certain legal restrictions are removed. Distilleries that suspend manufacture of whiskey can make alcohol in large quantities from sawdust and other wastes.

"The automobile fills a real transportation need. It is estimated 40 per cent. of the motor cars in America are owned and used by farmers. There are three times as many automobiles in Iowa, Nebraska and California in proportion to population as in New York State, Massachusetts, Pennsylvania or Illinois. Increase in car sales has been several times larger in agricultural states during recent years than in manufacturing states. Doctors, traveling salesmen, highway officials, municipal department heads, contractors and builders, and men engaged in many other lines find the automobile indispensable in their work. By its use they save many valuable hours daily.

"Efficiency is increased by use of time-and-labor-saving machinery. The automobile is essentially time saving. To insure success in the war the farmer, manufacturer, miner, contractor—all are urged to increase efforts and production. The automobile used in business is an economy—not an extravagance. Wholesome recreation in the open air is a great revivifier and invigorator. It enables the hard-working business man to continue intense efforts without breaking down. The automobile affords such recreation. President Wilson takes his relaxation in an automobile every afternoon.

"Greater passenger-mile service is rendered by the passenger automobiles in the United States than by the entire railroad or street railway system of the country. The 3,700,000 passenger cars, averaging 5,000 miles a year and three persons each, give a total of 55½ billion passenger-miles. At a rate of 2 cents per mile, this is worth $1,110,000,000 a year.

"Five acres of tillable land are required to support one horse; three acres to support a man. If each automobile takes the place of only one span of horses, the 3,700,000 cars release 37 million acres of land for production of food-stuffs for more than 12 million men—the total force employed in the war by all the allies. Approximately one million wage earners are employed in the motor vehicle industry. The majority are skilled mechanics. The automobile factories and their organizations of mechanics are an invaluable asset to the nation in military activity. They can be used for production of aeroplane engines, parts and complete machines and for manufacture of ammunition.

"Efficient transportation is essential to military activity. The armies in Europe are almost entirely dependent upon motor transport of supplies and ammunition and on motor ambulances for removal of the wounded. The American Army will need thousands of passenger automobiles for officers and tens of thousands of motor trucks for the Quartermaster's department.

"The billions of dollars to be raised for war purposes by bond sales and taxation will return almost immediately into circulation through payments for purchases of supplies for the government of the U. S. and the allied governments.

"Farm crop reports show record production; manufacturing is booming, prices are high, good salaries and wages are being paid and profits are large. False economy destroys efficiency. Elimination of waste applies to waste of time and effort as much as to material things.

"The national emergency requires that money shall be kept in active circulation, that labor shall be employed fully and that production of necessaries shall be greater than ever before. Men must make good wages, salaries and profits in order to subscribe for war bonds and pay excess profits and consumption taxes. Therefore, wise buying must go on.

"Stability of the industry is shown by the fact that stocks of the leading English automobile companies were higher on July 4, 1917, than on July 27, 1914, just before the war, despite the commandeering of cars and trucks and restrictions against the use of gasoline. German automobile companies have earned large dividends during the war. All European automobile plants have been extended during the war. Even if the use of passenger cars should have to be curtailed in the U. S. for a period,

Digitized by Google

the factories will be kept as busy as ever in the production of trucks, airplanes and munitions. After the war there will be a great world demand for cars and trucks. Exports during the last two fiscal years have amounted to nearly $100,000,000 yearly.

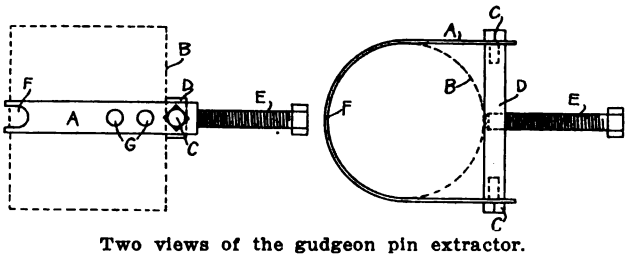
"Increased output of farm, factory, mine and forest products demands greater transportation facilities. Railroads are congested with freight as never before. Congestion is mainly at terminals. Trucks save manufacturer and merchant valuable time in making shipment to points within 100 miles.

"Retailers and the public are called upon to reduce local delivery service and release men for military and other work. Each motor truck and delivery wagon does the work of three or more horse-drawn vehicles, cutting down the cost and releasing two or more drivers and as many helpers. By use of motor trucks farmers can haul to market while keeping their horses working in the fields. They can make several trips with a truck in a day to one with a team or can haul two or three times as far. This brings into use good land formerly too far from market for profitable farming.

"One truck can do the work of five horses, on an average. This releases at least two drivers, and farm labor is very scarce and high-priced. It also releases 25 acres of land for the production of human foods. The 350,000 motor trucks in use in the U. S. release 7½ million acres—sufficient to support 2½ million persons. Averaging 50 miles a day with a load of only 2 tons for half this distance, the 350,000 trucks perform 5¼ billion ton-miles service yearly. At an average cost of 26 cents per ton-mile for haulage by road in city and country by horse-drawn and motor vehicle this service is worth more than a billion dollars. The War Department has definitely assured the N. A. C. C. that there is no intention of commandeering privately owned trucks or cars for army use. It is confident it can secure new machines from manufacturers as fast as needed and expects to award contracts so as to interfere as little as possible with sales and deliveries to business houses and individuals."

Tracing Electrical Troubles.

From Murray Fahnestock, Pennsylvania. — As electrical troubles are often more difficult to locate than to remedy, it is well to have a system for locating such troubles by elimination. Proceeding, as Sherlock Holmes hath it, by observation, knowledge and deduction.



If the electric starter fails to work, observe whether the electric horn and the lights are still in good order. If the lights burn brightly, it is reasonably certain that the storage battery is sufficiently up to par, and the trouble has been localized in the starting circuit. Opening the fuse box, the fuse for the starting circuit should be examined. If it is blown,—Stop! Inserting another fuse is the natural thing to do, but deduction tells us that the short-circuit that caused the original fuse to blow is probably there still. Thus it is only wasting a second fuse to insert it before finding and removing the frayed wire, the jammed motor, or other cause of the trouble.

The ammeter can also be used to great advantage, at times, in locating electrical troubles. If the ammeter indicates ten amperes, when the head lamps are turned on, and it normally indicates only four amperes, it is evident at a glance that there is something wrong with that particular circuit. A lamp that goes out intermittently indicates a loose connection or a broken wire. If the wire feels unusually flexible beneath the insulation a broken wire is probable.

By the use of a system of this sort, one can either begin at the battery, as the source of current, or at the lamps as the point where the current is utilized. Thus the cute currents can be traced to their short-circuits and the trouble easily eliminated.

Gudgeon Pin Extractor.

From M., in the Autocar.—Having occasion to remove the gudgeon pins from my engine, I found it impossible, without special means at my disposal, to move them without very considerable risks in the way of breaking the pistons. I therefore devised and made the simple little tool shown in the accompanying illustration. This consists of a band of flat steel, A, which partially encircles the piston, B, its ends being secured by two set screws, C, to a solid steel cross piece, D, through which passes a stout bolt, E. When the tool is placed in position, the bolt, as it is screwed through the block, tends to force the gudgeon pin out of the piston, the pin

Two views of the gudgeon pin extractor.

passing through the slot, F, formed in the steel strap on the opposite side. The tip of the bolt is hardened, so that it shall not be blurred when turning and pushing against the end of the gudgeon pin.

If two or three holes, G, on each side be drilled in the steel strap, the tool becomes adjustable for use on pistons of various sizes. The same tool is extremely useful when gudgeon pins are being refitted, for, although the strap would have to be made considerably longer than shown if the tool were to be used immediately after the gudgeon pin had been entered into the piston, I have usually found that it is the last quarter of an inch that gives the trouble, and in such a case the steel strap need be only slightly longer than shown in the sketches.

Gasoline for Priming.

When in need of a small quantity of gasoline for priming purposes and no other available way of securing it is handy, it can be secured by tying a string on one of the tire valve dust caps and letting it down into the supply tank through the filler hole. Care should be used that all dirt is wiped from the cap first. The amount of gas thus secured is usually just enough to prime one cylinder.

It is pointed out that if commercial firms using slow moving trucks find it to their advantage to carry liability insurance it would follow that it would be a much greater advantage to the owners of pleasure cars, which are operated at a much higher rate of speed to do the same thing.

WORLD TIRE STANDARDS.

English and French Manufacturers Desire to Co-operate with America.

In 1915 the Standards Committee of the S. A. E. tried hard to obtain some support from British and French tire makers for the setting up of international standards for solid tires. At that time the attention of the foreign manufacturers could not be obtained, but it now appears to be good reason to hope for an international standard within a reasonable time, according to the Automobile and Automotive Industries.

In 1915 W. H. Paull, of the Dunlop Company, the largest rubber company in Europe, and one of the largest in the world, visited America, and was in close touch with the international idea of the S. A. E. The British paper, Motor Traction, in a recent issue comments editorially on the subject of tire standards, and it is obvious that Mr. Paull is still anxious to see the work carried through, as the following will show:

"W. H. Paull, at a meeting of the Technical Committee of the motor industries, put forward a suggestion which was adopted by that committee to the effect that the time is ripe for an effort to be made to introduce an international standard of wheel and tire rims for solid rubber tires. The view is expressed that France, Italy, Russia and the United States will be willing to co-operate with Great Britain in the creation of standards, and this opinion has been forwarded to the Engineering Standards Committee.

Favor Army Standards.

"The subject is a very important one, which can be regarded either from the international or from the imperial point of view, or from both. If British manufacturers of vehicles and tires could unanimously agree to the adoption of certain standards the results should have a favorable influence upon manufacturing costs. Thus progress in this direction might be made advantageous to the British industry as compared with all others. If, on the other hand, it is thought to set up standards by agreement with the Allied countries, then the resulting effect upon cost of production would be beneficial to all those countries as against others not included in the group. The more comprehensive the scope of the movement the more advantageous it should be to motor users as regards both cost and convenience.

"Up to the present we in this country have allowed ourselves to drop rather behind in this matter of standardization of tires and rims. A good example has been set by the United States government, which, in placing huge contracts with American manufacturers of motor vehicles, has specified the provision of interchangeable rims on all road wheels, so that tires can be removed and replaced without difficulty by a mechanic and his assistant. In the specifications of the motor transport board of the United States army War Department for one and a half and three ton vehicles for the use of the army the following paragraphs appear, and we are certain they will interest our readers:

English Favor Plan.

"The wheels shall be of suitable size and design for the use of 36 inch by 4 inch single solid S. A. E. demountable rubber tires on front wheels and 36 inch by 7 inch single solid S. A. E. demountable tires on rear wheels.

" 'The steel fastenings for demountable tires shall be constructed in accordance with drawing Q. M. G. O., No. T-101. Trucks will positively not be accepted having tires or tire fastenings which differ from those herein specified.

" 'All tires shall be best quality solid rubber tires on hard rubber base with S. A. E. steel rims.'

"It is evidently incumbent upon us in this country to standardize either rims and tires exactly in line with those adopted by the United States, or else something decidedly more advantageous and better from the point of view of the user. The question, then, that deserves most serious consideration is whether we could not adopt as a standard a form of detachable tire and rim which would enable tires to be easily changed without the use of special machinery and without necessarily removing the vehicle wheel.

To Overcome Rust.

"From time to time various designs have been brought forward conforming to these requirements, but one of the difficulties that have stood in the way of their extended use has been the tendency for the joints, on which easy dismantling depends, to rust up fast during prolonged use upon the road. It ought to be possible to overcome this trouble by suitable research and experiment. We can imagine few subjects more deserving of the prompt attention of the technical committee of the motor industries than this question of tires and rims. The necessary reform can only be brought about by a body so influential and so certain of general support as to be able in effect to compel individual manufacturers either of tires or wheels to fall into line. The committee now existing should, particularly in view of its relations with the Engineering Standards Committee, be in a position to carry through against all opposition any program as to the desirability of which it is unanimously agreed.

"Some time ago notice was given of the formation of a joint technical committee of the Institution of Automobile Engineers and the Society of Motor Manufacturers and Traders, on which government departments were also to be represented. The committee has just held its third meeting, at which A. A. Remington, of the Wolseley Co., was elected chairman for the year and Lieutenant-Colonel R. K. Bagnall-Wild, vice-chairman. A resolution was adopted to the effect that the time is now ripe for a serious effort to introduce an international standard of wheel and tire rims for solid rubber tires. It is believed that France, the United States, Italy and Russia would be willing to co-operate with Great Britain in this matter. A copy of the resolution was ordered forwarded to the Engineering Standards Committee.

Aid to Engineers.

"It was decided to collect data on several subjects of proposed research, and a suggestion has been made to the committee that a Bureau of Technology be established, where technical information regarding all branches of the motor industry might be obtained and which might issue a periodic prècis of up-to-date information relating to late scientific advancement and its bearing on automobile engineering. Such a service would be of great value to automobile engineers, but it would require the finan-

Digitized by Google

cial support of the manufacturers, though it is quite likely that the government would make a substantial contribution through the Department of Industrial Research.

"Another proposal is to the effect that the committee lend its aid for the better co-ordination of engineering training, and steps to this end have already been taken. The committee is represented on all the automobile sub-committees of the Engineering Standards Committee and is doing all in its power to help the work of standardization."

AMONG MASSACHUSETTS GARAGES.

A One-Legged Man Achieves Success in Repairing—Crossing Railroad Tracks.

BY JAMES F. HOBART, M. E.

This forenoon, I saw two one-legged men, each of whom were making their living under very different conditions and want to leave the matter to readers of this magazine as to which of the two men had the right spirit. One of the men was comfortably disposed under a railway bridge which crossed a well traveled road. He had a box of pencils into which some of the passers-by tossed a nickel or a dime, often without stopping to take a pencil—costing ten cents per dozen wholesale—in return.

The man must make a good thing of it for he is there day after day, comfortably seated upon a sack which was apparently well stuffed with some soft substance and there the man sits with his stump of a limb prominently displayed in a manner which no passer-by can help beholding.

The other man is doing repair work in a garage and a mighty lively proposition he is too. He uses a crutch, but for all of that he seems to get around and handle tools as well as the other man in the shop who has both feet. The single foot man can get under a car fully as quickly as a man with two feet.

The crutch seems almost to take care of itself and is almost entirely managed by the arm, above the elbow, of the side from which the foot is missing. This leaves both hands free for using tools and when working on a car, the crutch is usually discarded unless some stepping around must be done.

A steel hook permits the crutch to be hung up when not in use and the man will catch the crutch hook over a convenient part of an automobile, where the crutch is handy to the hand, and then go on with his work, standing on one foot, but able to catch up the crutch in an instant whenever it is necessary to step along to get tools or material.

The one-legged repair man passes the bridge beggar twice daily and never fails to berate him soundly for his manner of living. It is an open question, as yet, which man receives the greater income but there is no question whatever regarding which is the most respected in the neighborhood. Furthermore, the example may be a valuable one to some men who have had the misfortune to lose one of the lower limbs and are trying to select some method of earning a living where the great handicap will not put them out of the running altogether.

To be sure, a whole lot depends upon the individual, but there is a chance in the care and repair of automobiles which many a war veteran can avail himself of and thereby avoid the "pencil-begging" which the other man affected. And the garage worker obtained a whole lot more of pure sympathy than the pencil worker was able to get hold of, showing that the public, as usually is the case, was quick to put their business into hands which really deserved patronage.

Handle Fine Tools Carefully.

It always makes the writer feel badly to see good tools abused, and recently when a man tested out a tire he was filling and threw the tire gauge on the floor while more air was pumped in, it "went against the grain" to see a good tool thus abused, particularly by a man who was supposed to know better.

The workman was—and that makes the matter all the worse—a "cod-fish" Yankee (the writer is one, too) and therefore is supposed to know how to handle and take care of tools. But he threw the delicate gauge on the floor with wrenches and hammers with never a thought that the tube which contained the piston and spring might be slightly dented, thereby putting the gauge out of business. The incident calls to mind a circumstance which happened long ago between a mechanic and his son. It appears that someone wanted to borrow a tool from the son and the older man expressed his opinion of tool lending as follows: "Never lend a tool to a man who gets less than $2.50 per day, for he is not capable of taking care of tools. And never lend a tool to a man whose wages are more than $2.50 per day, because he is able to buy tools of his own!"

Safe advice, that, and it should be enforced by garage and repair shop men who lose dozens of tools annually through good lending and poor returning. There is another tool, besides the tire pressure gauge which receives many a hard knock which it is not entitled to, and that is the "battery-tester", that handy little watch-shaped tool which indicates at a touch whether a dry cell will yield 30 amperes or zero. Handle this tool carefully and it may be depended upon for a good many years, but let it knock around in a tool or a cigar box with a lot of screws and nuts and you never will know whether the gauge is to be depended upon or not.

Driving Across Railroad Tracks.

There is a railroad crossing almost under my window, as I write this story. It has caused many a broken spring and nobody knows how much damage to transmissions and gears by the sudden shocks due to incautious driving. To be sure, it is the driver, not the crossing, who is to blame for the many breakages which have been laid to this track crossing, and this crossing is no worse than dozens of other crossings; particularly those which happen to be located on a curve. And to make the matter worse, as is the case with this crossing, the highway crosses the railway track on a grade.

When the railroad track is straight, there is apt to be very little trouble at crossings, but where the crossing is laid down upon a heavy curve, there is sure to be trouble unless the car driver is wise to a few facts and looks out for the trap which may exist at the crossing. As stated, when the track is straight, all the rails are of the same height and the planking, together with the gravel filling between the two or more tracks, is smooth and level. But when the track curves, something happens as shown by the drawing. The rails of each track. A and C, are on the same level with each other and rails B and D are also level with each other; but

Digitized by Google

rail B is not on the same level with A, and D is higher than C, thus making the crossing into a series of short inclined planes as shown.

When a car comes down the grade F, the inexperienced driver, seeing an apparently smooth railroad crossing before him, is pretty apt to let the car come down at a fair rate of speed, intending to go still faster when the lower pitch is reached at E. But all is not smooth coasting as it appears from the pitch F.

A railroad track is made up of "curves" and "tangents". On each and every curve, the outer rail must be elevated a certain amount, depending upon the sharpness of the curve, in order to prevent the locomotive and cars from toppling off the track should they undertake the curve at a high rate of speed.

Rails A and C are shown upon the same level, and it is also apparent how rails B and D have been raised to keep the trains on the tracks. This makes it "up-hill" from A to B, down-hill from B to C, up-hill again from C to D, and up-hill still more from D, up the pitch F. Therefore, when a car coasts down incline F, it finds itself in a bad "potato patch" upon the crossing and before the speed of the car can be checked, it has been bumped two or three times very badly, and limps off down the incline E with perhaps a broken spring or some worse trouble.

Thus a car driver cannot be too cautious when approaching a railroad track, particularly one upon

Illustrating how railroad tracks on curves create bumps and depressions.

a curve of the railroad and especially upon a pitch in the highway. It is a well established driving rule that a car should always be under good control when approaching a railroad crossing down a pitch of the highway.

Oiling a Leather Auto Top.

There are "store" preparations which may be bought in required quantity for treating automobile tops which chance to be made of real leather, but don't let the top go without dressing just because you can't get out to purchase liquid to fix the top with. Just procure some neat's-foot oil, and treat the leather with it.

If you cannot obtain the neat's-foot oil, then go to your butcher and have him save for you a dozen or more feet from the beef cattle he kills. Put the hoofs into boiling water until the horn covering can be pulled from the feet. A good strong hook is necessary for this purpose and one similar to that used by freight handlers will do the business nicely.

I am afraid that the makers of commercial neat's-foot oil have a habit of grinding or crushing the feet with hoofs and hair all on, but the best oil is made after the hair and horn have been removed. Place the cracked-up feet in a kettle of water and boil until the oil has worked out of the flesh and bones of the feet. In commercial work, a filter press is used to separate the oil from the scraps, but if you "try" out oil for yourself, you can make the separation by twisting the scraps in a bit of cloth and then squeezing through the fabric, as much of the oil as is possible.

When it comes to the actual oiling of the leather, don't be stingy with the oil or be afraid to put on a whole lot of it. In fact, just "slather" it on with a rag or sponge and put on all that can be made to stay without running off. There are usually corners where it is hard to make the oil penetrate. For such places, use a small brush and see that a flood of oil is driven into each and every corner or fold of the leather.

After the oil has remained for some time on the leather, wipe off all that will come and polish the top with the rag used for removing the surplus oil. An auto top treated occasionally in this manner will not wear out under many years of use, neither will it crack.

Wasting the Oil.

The writer was riding behind a Ford car recently when a large "six" passed and a cloud of smoke and gas almost completely enveloped us and our little "flivver". "There goes a lot of good oil to waste", said the other party in our car. "It is strange that people will not learn to use the proper amount of oil. That man is getting rid of twice as much oil as is necessary and not only is he wasting good oil and gasoline for which he has to pay big money, but he is also making himself trouble in several ways. Not only is he overheating the engine, but he is overworking the radiator, causing the water to boil out fast and over-loading the engine as well as over-heating it. And there is another trouble coming to him which is the worst of all. By using too much gas and oil, he is laying in a bad deposit of carbon on the pistons and the cylinder heads, which will cost money to remove. I tell you, son, too much gas and oil are mighty bad things to have in an automobile engine.

"Then there is another thing. When the average man is starting an automobile engine, he is very apt to use too much gasoline, too rich a mixture. When the mixture is too rich, there can be no explosion in the cylinder for a gasoline-air mixture does not become explosive until there are certain proportions of air and gasoline. Therefore, if the priming be too lavish, or the carburetor is set for too rich a mixture, the engine cannot be started any more than if it were filled with water and air instead of gasoline and air.

"More times than one, I have started a balky engine, which had been cranked time after time—with the oil jet wide open—by shutting off the gas completely and then spinning the engine a few times, after which the spark should be thrown on, a little gas turned on and away goes the engine, almost every time."

"Fording" the Hills.

I have recently been sojourning among the hills of northern Massachusetts where the valleys are so deep that they have to put more straps on the horses to prevent the animals from falling through the collar when going down hill! At least that dope is handed out free to visitors by the same old Yankee who tells you how much better the farming is in Massachusetts than in New Hampshire, where they have to hold sheep up by their tails so the muttons may get their noses down among the rocks where the grass grows!

But the old Yankee in question said that they don't have to ford the rivers any more, they have bridges, but they do have to Ford the hills and he

Digitized by Google

did wish that "Henry" would just put one more speed in his machines. The above-mentioned Yankee had a Ford car, of the vintage of 1912, with which he did a whole lot of hill-fording and picked up a good bunch of change in hauling "S. V.'s" to and from the trolley line and the summer hotel at the lake.

"What is an 'S. V.'?" the old Yankee remarked as he stamped his rubber boots on the railway station platform. The old settlers of northern Massachusetts and New Hampshire always stamp their feet each and every chance they get. They forget themselves during the short red-hot summer months and really imagine they are stamping off snow as they climb upon the depot platform.

"Why do they wear rubber boots in summer? Why, stranger, how could a New England Yankee ever think of wearing anything else? Isn't the dew thick enough in the morning to float a Missouri river steamboat? And don't he have to wear boots of evenings to keep the 'skeeters from biting holes in his ankles? Sure he must wear rubber boots at plowing, hoeing and field work, therefore it isn't worth while to change foot wear just for two or three hot summer months, or while he is at church, or during the one day on which he goes to the beach. No, it doesn't pay to change foot wear for those few occasions, therefore the rubber boots are worn in New England Farmerville, all the time.

"My Ford is a crackerjack," said the old Yankee as he spat unerringly at the head of a chicken which ran under the automobile. "I sure will have the 'old boat' running fine by next month. I found a place this morning, where the gasket had blown out a little and all the 'compression' from one cylinder was sneaking out through that hole. But I got home all right on the other three cylinders. Say! I am going to take off the cylinders, clean up the joint with kerosene oil and sand paper, then I will make a new gasket from the top of one of my old rubber boots, and I'll bet you an ear of corn that my car will climb the meeting house hill better than Sile Haygrass can do it in his 'new' second-hand machine!"

The farmer was using his Ford for all it was worth, carrying passengers over the rock strewn trails which are called "roads" by the native born. The water all runs down hill right in the middle of the road because the sides are higher than the middle and the water can't get out of the road save at the bottoms of the hills. At every few feet will be found granite ledge rocks cropping up to try the temper of drivers, springs and shock-absorbers.

"I'm packing a stone hammer this trip," said the Old Farmer as he cut off the spark in front of the village store. "I have to knock the tops off of some of those rocks or I won't be able to get the car past them. They are fierce and get worse every year. I wish the Road Commissioners had to be pulled over those rocks by the heels until they would break them out of the roads.

"Say, mister," the Old Farmer continued, "I have to get some new pins in the pistons of my automobile engine for the last time I had the pistons out the little pins which go through the pistons and the connecting rods were loose and they make that funny rattling noise which you hear when the engine is running. Do you think I can put some pieces of tin in beside the pins in the rods and in the pistons, or how had it best be fixed? Sam Smith told me that the only way to fix it right was to have the pin holes reamed out and some new pins made larger than the old ones which would fit tight in both the piston and the rod.

"But I don't see why I can't file the holes out a little bit with a big rat-tail file. Then I have a broken crowbar and one end of it is just a little bigger than the pin-holes. After they have been filed out round, why can't I fit in pieces of the crowbar handle for new pins?"

The above is a fair sample of the ways and means of automobile repair in some parts of the country. Is it not almost a miracle that cars stand up under the rough usage and still rougher repairs? That they are able to meet the demands made upon them with too little breaking down of the mechanism? A car with a boot-leg gasket and crow-bar piston pins, certainly would be a rare object lesson in the great problem of getting there—and keeping there!

MOTOR CAR EXPORTS FALL.

Embargoes Affect Shipments but Loss in Trucks Is Offset by Passenger Cars.

Figures issued by the Department of Commerce show that during the twelve months ended June 30, 1917, the United States exported 80,811 automobiles and motor trucks, valued at $90,958,243, as compared with 77,499 cars valued at $97,465,811 during the preceding fiscal year.

The increase in number of cars exported is due to the larger shipments to most countries outside of Europe, which more than offset the decreases in exports to Great Britain, France and Russia due to import prohibitions and lack of shipping facilities.

The fact that the aggregate value of exports during the last fiscal year was less by $6,507,000 than in the preceding year, while the actual number of vehicles exported was greater by 3,312, is due to decreased shipments of trucks for war purposes, the average value of which is much higher than the average value of passenger cars exported to countries outside of Europe.

While the number of trucks exported fell off 5,288 in the year and their aggregate value was $14,468,-233 less, the shipments of passenger cars increased by 8,600 and their value by $7,960,665. Great Britain and France were still our largest markets, despite their heavy falling off in purchases. The former bought $18,508,442 worth last year, mostly trucks, as against $26,147,832 worth in the previous fiscal year. France's imports were nearly all trucks and amounted to $14,691,460 as compared with $19,137,904 in the twelve months ended June 30, 1916.

Owing to shipping difficulties and internal political troubles, Russia's imports fell from a value of $15,686,874 in 1916 to $6,371,982 in the last fiscal year. Aside from the European countries, Canada is America's best customer for motor cars, having increased her purchases by nearly $4,200,000—from $7,280,151 in 1916 to $12,088,787 in 1917. Next comes Asia and Oceania, with imports of 9,716 cars valued at $10,093,720 last year—an increase of $1,450,927. Australia follows. with 5,000 valued at $4,213,874. The British East Indies increased their purchases from $2,307,739 to $3,617,351. In the Americas. after Canada, the West Indies were our best market for automobiles, to the extent of

Digitized by Google

$4,072,647, an increase of $1,248,735 over the year before.

The most remarkable increases, however, are shown by Mexico and the South American Republics. Mexico's commercial recovery is reflected by an increase from $409,700 to $1,833,975 in the year. Argentina's imports reached nearly 2½ million dollars. Brazil's trebled. Chile's prosperity from her nitrate mines resulted in an increase from $576,777 to $1,982,538. The rest of South America took automobiles to the value of $1,804,827 as against only $698,911 the year before. In addition to automobiles, the United States exported in the last fiscal year 23,435 automobile engines valued at $2,844,406; tires worth $12,330,201, and parts worth $27,284,932.

Takes the Place of the Railway.

A resident of this city, who spent the past several days in Everett, declares that there is enough freight passing over the Lincoln Highway daily to load a full-sized railroad train. The freight is hauled on giant tractors and motor trucks, running between Chicago and New York. It is claimed by those in charge of the work that the new method of transportation is more certain than railroads, owing to the overworking of the latter.

The tractors and trucks run in groups of six and eight in charge of a superintendent and carry all manner of freight, including meats and all sorts of food stuffs. The transportation of new automobiles by the highway route has also become a popular way of moving the machines from factory to purchaser.—Altoona (Pa.) Times.

Weights of Ford Cars.

When shipping Ford cars, or when making changes on the chassis or other parts, it is often desirable to know the exact weights of the different types of the Ford car.

Weight of runabout	1,380 lbs.
Weight of touring car	1,490 lbs.
Weight of coupelet	1,520 lbs.
Weight of sedan	1,700 lbs.
Weight of town car	1,700 lbs.
Weight of chassis complete less lamps and fenders	1,020 lbs.
Weight of motor and transmission	360 lbs.

To these weights add 20 pounds, if the motor is fitted with a cast iron transmission cover.

Runabout body	300 lbs.
Touring car body	400-415 lbs.
Coupelet body	450 lbs.
Sedan body	550-600 lbs.

Care of Tire Tubes.

It is difficult sometimes to determine just when a tube is unfit for further use. Porosity in a tube usually indicates that it has attained its three score and ten. At this stage very small cracks can be observed in the rubber if it is stretched and examined carefully. The next development is splitting when the air pressure becomes too great for the tube to bear.

If the rubber in a tube is "live" it may successfully bear as many patches as a beggar's coat. But due care must be exercised in the vulcanization of the patch to the tube, that too large a portion of the tube around the patch is not cured. If portions of the tube have been over-cured in patching operations, disaster is sure to follow.

Lack of proper care of the tube is responsible for most of the troubles tire users experience. Sufficient talc between casing and tube prevents the generation of heat which vulcanizes the tube to the fabric of the casing. Tube splitting is occasioned by the slipping of the tube between the casing and the rim, which soon results in a "pinch." The remedy is careful applying.

The protection of spare tubes is a matter that many tire users pass over too lightly. Usually spare tubes are folded and carried in the tool box, where they may come in contact with grease, oil and tools.

The grease and oil greatly reduce the quality of the rubber, while the tools many times cause the tubes to become chafed and worn and unfit for use.

Light Weight Cars.

At last the light-weight car is coming into its own. Not that it rides as easy on rough roads, but its saving of tires, fuel and general wear is of decided advantage. At the recent Memorial day race in Cincinnati the aluminum products of the Chevrolet brothers did not have to make a stop for tires, although there were three of them in the race. Two of the three, those which finished first and third did not have to make a stop for any purpose. The heavy Mercedes driven by Louis Fontaine had to make four tire stops out of the ten which were made. The Hudson which finished second did not stop. The 100 m. p. h. pace did not seem to trouble the light cars anywhere near to the extent that it did the heavier cars, either in tires or mechanical troubles. Where mechanical failures occurred they were due to trivial details rather than basic errors in design.

Denver to Hold Motor Car Show.

Denver, Colo., is to hold a motor car show. The event will be under the auspices of the Auto Trades Association and will be held the week of November 12-18. G. A. Wahlgreen is to have charge.

Pertinent Hints.

Do not neglect to take a few spark plug cores with you on your trip. The metal parts of a spark plug will last almost indefinitely, but the cores must break in time, and that usually means buying a new spark plug. As the cores can be bought for a fraction of the cost of a new plug, it means economy to carry a few with you. Also carry a few extra gaskets.

Large corporations employing many drivers have found it to their advantage to carry liability insurance as a safeguard against the carelessness of their employes and also as a means of stopping numerous claims for damages that might be brought against them.

When you get a letter that makes you hot under the collar, makes you clench your fist and pound your desk—call your stenographer and dictate a sassy reply. And then destroy both letters. The advantage of this plan is that it gives an outlet to the bile in your system.

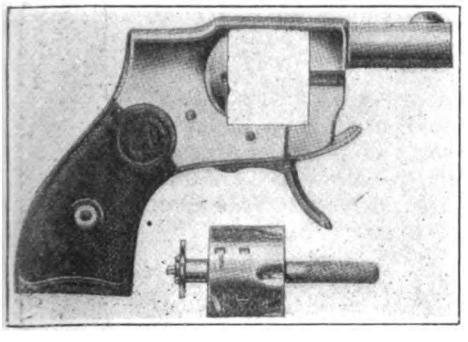
NEW AND INTERESTING THINGS IN MOTORDOM

Two Good Sedgley Specialties.



Many of our readers are already familiar with the line of ratchet socket wrenches for automobile use which are manufactured by R. F. Sedgley, 2311-13 No. 16th Street, Philadelphia. We illustrate herewith the Hexall ratchet

Sedgley Hexall Ratchet Socket Wrench No. 1.

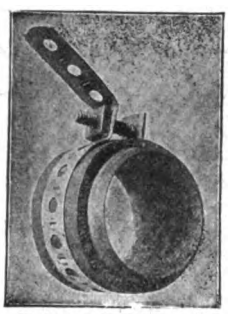
socket wrench No. 1 made by Mr. Sedgley. This set contains a 7-inch steel forged ratchet handle, also two screwdriver bits; 7-inch extension bar; eight hexagon sockets, and four square sockets. These sockets are adapted to a wide range of A. L. A. M. and U. S. standard bolts and cap screws. The same manufacturer has a complete line of ratchet socket wrench sets covering every conceivable size of bolt or nut and every make of automobile.

We also illustrate the Sedgley Hammerless Ejector Revolver, an extremely handy pistol for any motorist. The new model here shown has the simplest possible method of removing the shells from the cylinder, yet it still retains the strength of the solid frame with all the conveniences of the swing out, without their disadvantages. This pistol is an accurate shooting piece and its length is overall 4 inches; weight, 6 ounces.

Sedgley Hammerless Ejector Revolver.

It is equipped with a hammerless folding trigger, interchangeable parts, and new one-piece main and trigger spring. It is no common thing for a motorist to be attacked and robbed, and some means of defense is only a sensible precaution.

The Consolidated Engine Heater.



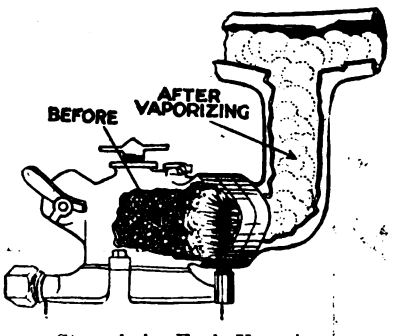
This is a device which makes starting a car easy in cold weather. It is a durable, safe, economical and convenient electric heater to keep the engine and carburetor warm. This heater may be attached to the electric light socket in your garage and start in a jiffy. The manufacturers contend that it is not necessary to go to the expense of heating your whole garage, and they state that this safe and efficient little electric heater applies the heat just where you want it, under the hood of the car. Readers who are interested should write for prices and full particulars direct to the manufacturers, The Consolidated Car-Heating Company, Albany, N. Y.

New Chief Engineer for Stanley.

Mr. C. E. Broad, who has lately rejoined the engineering staff of the Stanley Motor Carriage Company, Newton, Mass., after an absence of seven years, has just been made chief engineer of the company. The engineering board now includes Mr. Broad, S. C. Mussey and C. F. Stanley. In gas car circles, Mr. Broad is best known for his work in truck design for the Packard Company, but his specialty has always been steam, and he has been active in steam passenger car and truck design for twelve years.

The Universal Hose Clamp.

The Universal Hose Clamp illustrated herewith has several important advantages. If your experience is like that

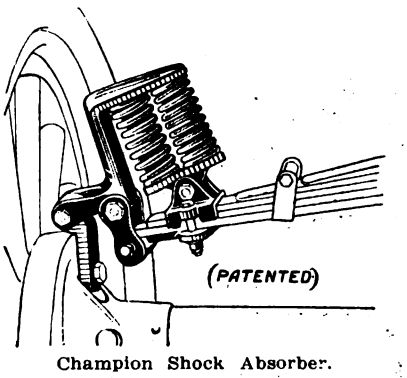


The Universal Hose Clamp.

of the majority of garage men you have been confronted with the unpleasantness of requiring a hose clamp to fit a certain size of clamp in stock. The Universal Hose Clamp is adjustable and will fit any size hose about an automobile. It is made from strong cold-rolled steel and comes in ribbon form with screw and nut attached and is pliable enough to easily wrap around and conform itself to the shape of a hose. The clamp ribbon has holes half inch apart along its middle portion, and in these holes lies the secret of its adjustment. Anybody with mechanical ingenuity will understand the method of adjustment by inspecting the cut which appears with this article. The Universal Hose Clamp is made by the Universal Industrial Corporation, Hackensack, N. J., to whom all inquiries should be addressed.

Stransky's Fuel Vaporizer.

This is a new device which is manufactured by the Stransky Mfg. Co. of Pukwana, S. Dak. The manufacturers of this invention state that while the average carburetor will only vaporize from 50 to 75 per cent. of the fuel, the Stransky Vaporizer will vaporize close to 100 per cent., thus giving 25 to 50 per cent. more mileage, also more power and speed with no carbon. This vaporizer works automatically, no spring, diaphragm, or shutters, and it has only one working part. the steel ball valve. It is made entirely of brass and steel and guaranteed to last a lifetime. It is also easily applied to the car. There are no holes to drill or tap and no special tools needed. Any farmer with an ordinary wrench can attach one in five minutes' time. This vaporizer sells for only $3.00 on an extremely money back guarantee. The car owner is to be the judge and jury,



Stransky's Fuel Vaporizer.

and if not satisfactory, the vaporizer can be returned and your money will positively be refunded. Twenty thousand of these vaporizers have already been sold and there is open territory for good dealers in several sections of the country. One state agent has been making over $500 per month, selling this c'e. and proof will be submitted that this vaporizer is a wonderfully quick seller. Readers who are interested should write direct to the manufacturers as soon as possible, before all the good territory has been taken.

Champion Shock-Absorber.

We illustrate herewith the new shock absorber for Ford cars which has recently been placed on the market by the Champion Shock-Absorber Sales Company, Inc., Indianapolis, Indiana. A set of Champion Shock-Absorbers features eight-coil compression springs which absorb all road shocks and jars by their compression. "Champion" is different from all other Ford shock absorbers as you ride on eight large coil springs, making the Ford car as easy

Champion Shock Absorber.

riding as any high price luxurious machine. The manufacturers of this device are so confident as to its merit, that they will give any Ford owner a ten-day trial on a set of "Champion" Shock-Absorbers to prove their guarantee to make the Ford ride equal to any $5,000 car. Readers who are interested should write for prices and further particulars to the main office of the company at Indianapolis.

JOHNSON'S CARBON REMOVER

Cures 80% of Engine Trouble

A dose of Johnson's Carbon Remover—The Engine Laxative—will make your motor run like it did the first 500 miles—quietly and full of "pep"—And your gasoline consumption will drop from 12% to 25%. You will save from $3.00 to $5.00 over any other method.

Takes out the Knock

You Can Take the Hills on High Without a Knock

if you will keep your motor free from carbon with

JOHNSON'S CARBON REMOVER

That knocking in your engine—difficulty you have climbing hills—poor pick-up—pre-ignition and lack of power will all be overcome.

You Can Do It Yourself

For 25c—five minutes' time—and with no labor, you, yourself, can remove all carbon deposits. Pour an ounce of Johnson's Guaranteed Carbon Remover into each cylinder—allow it to remain two to twelve hours, then drive your car 10 or 15 miles. Results will surprise you.

Use It Every 1,000 Miles

If you will use Johnson's Carbon Remover at regular intervals, giving carbon no chance to accumulate, you will eliminate most valve trouble and your engine will always be at its highest efficiency.

If your dealer cannot supply you with Johnson's Carbon Remover, use attached coupon.

Write for our folder "Keeping Your Car Young"—it's free.

---- *$1.00 Special Offer $1.00* ----

S. C. JOHNSON & SON, Dept. AL 9, Racine, Wis.

I enclose $1.00 for which please send me by prepaid express enough Johnson's Guaranteed Carbon Remover to thoroughly clean an ordinary four-cylinder motor four times.

JOHNSON'S PREPARED WAX

Now Made in Liquid Form

We are now making Johnson's Prepared Wax in ***Liquid Form*** as well as Paste—so that it may be more easily polished. Johnson's Prepared Wax ***Liquid*** is exactly the same as our Paste Wax except that it is a liquid. Apply with cloth, brush or spray.

Is Your Car Dirty, Grimy and Unsightly?

DO you know that you, yourself, can make it look almost like new and save the cost of revarnishing? All you need is Johnson's Cleaner and Johnson's Prepared Wax ***Liquid.***

JOHNSON'S CLEANER

entirely removes all stains, scum, road-oil, tar and grease from body, hood and fenders. It doesn't injure or scratch the finest varnish—simply cleans and prepares it for the Wax polish.

Absolutely Dust-Proof

Johnson's Prepared Wax Liquid gives a hard, dry, glasslike polish which does not collect or hold the dust. It preserves the varnish and protects it from the weather, adding years to its life and beauty. It covers up mars and scratches—prevents checking and cracking—sheds water and makes a "wash" last twice as long.

Johnson's Prepared Wax Liquid is very easy to use—it polishes instantly with but very little rubbing. You can go over a good sized car in half-an-hour.

Quarts.....$1.40 Pints.....$ .75
East of the Rockies

If your dealer cannot furnish you with Johnson's Automobile Products, we will pay the expressage to any point in the United States east of the Rockies.

Write for our folder "Keeping Your Car Young"—it's free.

Use of Two Spotlights Coming Into Vogue.

"Have you noticed how many cars are using two spotlights?" asks Mr. Bert G. Cochrane, sales manager of Howe Manufacturing Company, 1732 South Michigan Avenue, Chicago. The principal reason for this is the fact that so many motorists utilize the services of the spotlight entirely for a driving lamp and therefore feel the need of a second lamp for the many other needs which a spotlight fills.

The motorist who does considerable country driving has found that the spotlight makes the finest kind of a lamp for directing a strong light on the road

Car Equipped With Two Howe Spotlights and Howe Electric Lighted Flag Holder.

40 or 50 feet ahead of the car. This enables him to see the sink holes and bumps in time to slow down and avoid a shaking up.

Another reason for the growing popularity of the spotlight as a light for driving, is the growing sentiment against the use of glaring headlights which blind the driver of the approaching car. The spotlight casting its light down as it does, absolutely causes no glare.

The lamp used for driving when two lamps are on the car, is the one on the side away from the driver. This leaves the other spotlight ready for the driver to turn in any direction where he wants light for the purpose of reading a passing sign, to watch the side of the road where it is narrow and dangerous, to explore the road several hundred feet ahead, or for any of the many other purposes where a movable light is desired.

The Fremont Demonstration.

Debarred from participation in the authorized demonstration of tractors at Fremont, Neb., because the Smith Form-a-Tractor Company does not build a standard type tractor, the company was determined, nevertheless, to be present and to show the thousands of farmers and dealers who attended the event what the Smith Form-a-Tractor could do. A tract of land, therefore, has been rented between the city of Fremont and the regular demonstration grounds, on which the Smith Form-a-Tractor, under the efficient direction of Jas. A. King, will establish its right to consideration in the tractor world.

The Smith Form-a-Tractor does not enter the field as a competitor of the standard type tractor. It is in a class by itself. It comes to the farmer as the cheapest and most effective solution of his power and help problem. It offers to utilize the power he already has upon the farm in the most effective and economical way for him. At the cost of a single good horse it offers to do the work of four horses in all essential farm operations and to do the work at one-fourth the cost of maintaining the four horses it will displace.

The Smith Form-a-Tractor talks in terms of power, proficiency and profit to the man who farms 40 acres as well as the man who farms 400. The work it will do for the farmer entitles it to his consideration, and this is why the Smith Form-a-Tractor Company will make an independent demonstration at Fremont where the intelligent and discriminating farmer may compare the work of a tractor which can be nothing but a sure economy on his farm with the work of tractors which can be only of doubtful economy unless he be an extensive farmer. The Smith Form-a-Tractor is made by the Smith Motor Truck Corporation, Michigan avenue and Sixteenth street, Chicago, Ill.

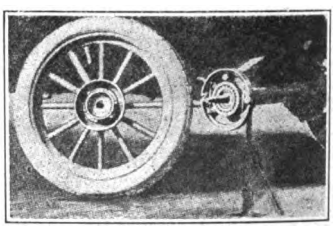
New Foundry for Adamson.

The Adamson Manufacturing Company, East Palestine, Ohio, makers of the well known Adamson tire vulcanizers, have erected a large addition to their foundry building, and are now manufacturing Ford brake shoes, lined and unlined, light gray iron castings for automobile parts and other automobile specialties, to be announced later.

Cork Inserts Stop the Slip.

The postage stamp has won fame because of its faithfulness in sticking to its appointed work. It has a worthy rival in cork, in its ability to hold its grip. Almost every other substance known to man becomes polished under constant friction and wear. Not so with cork. It avoids becoming slick and slippery as naturally as a duck sheds water. Ordinary transmission fabric becomes polished and slippery from its service in the Ford car. So does the usual fan belt. And then what happens? They slip. They don't do their work as good as when new. There is grabbing and slipping which causes chattering and vibration in the transmission action. The fan belt cannot revolve as fast as it

Cork Insert Fan Belt and Brake Band Lining.



ought when the belt slips. That means the motor isn't cooled as it should be. Cork inserts are a perfect and permanent antidote for slipping. The buttons of cork never become polished or hard. They never lose their ability to grip. That's why Cork Insert Transmission Linings make the Ford brake brake, and Cork Insert Fan Belts keep the Ford fan fanning. These belts are made by the Advance Automobile Accessories Co., Chicago, Ill.

Hercules Auxiliary Bearings.

The Hercules Auxiliary Bearings were designed for use, in combination with a bell sprocket housing where the Ford rear axle is used as a jackshaft on Ford chassis converters, for converting the Ford car into a one or a one and one-half ton truck. No changes of any kind are necessary in the regular Ford construction, to install the Hercules Auxiliary Bearings.

The Hercules Auxiliary Bearings consist of two special high duty type, combined radial and thrust bearings, capable of carrying a load of 3,000 pounds and are dust proof.

These bearings are mounted on the outer ends of the Ford rear axle hous-

Hercules Auxiliary Bearings.

ing and engage an offset sprocket bracket which is fitted in place of the wheel on the axle shafts.

When the sprocket brackets are in place on the axle shafts, they engage the outer race of the Hercules Auxiliary Bearings, thus carrying the entire driving load on the axle housing, removing all strains and jars from the axle shafts, caused by the slap and drive of the chains.

When the Hercules Auxiliary Bearings are installed, the axle shafts do the driving and the load is carried on the axle housing. These bearings are made by the Hercules Auxiliary Bearing Works, 327 So. La Salle Street, Chicago, Ill.

Stewart-Warner Clock in New Hands.

The Waverly Novelty Company, Bessemer Building, Pittsburgh, Pa., has purchased from the Stewart-Warner Speedometer Corporation their electric clock business, and all old contracts will be filled hereafter by the Waverly concern. We understand that improvements will also be made on the original model of this clock which will now be put out under the name of "Waverly."

Wire Wheel Corporation of America.

The Wire Wheel Corporation of America has established a patent department at their general offices in Buffalo, N. Y. Mr. B. M. Kent of Washington, D. C., has been retained as Patent Counsel for the company and will have charge of the work of the department.

What One Chalmers Dealer Says.

We take great pleasure in reproducing a letter which was recently received by the Chalmers Motor Company, Detroit, Mich. This letter is from the L. H. Rose-Chalmers Company of San Francisco, California, and it reads as follows:

"Give me the Chalmers line on its remarkable sound basis of today for the rest of my years, and I shall, indeed, be contented."

Outwear three sets of ordinary linings

They Make the Ford Brake BRAKE!

ADVANCE CORK INSERT

TRADE MARK REG. COPYRIGHTED 1917

TRANSMISSION LININGS FOR FORDS

Uncertain, jerky brake action is replaced by positive, sure-action and velvety smooth braking, the minute you equip a Ford with Cork Insert Transmission Linings. When you go into low, there is a quiet, gliding getaway, like high priced cars, instead of a lurch. In addition, Cork Inserts wear three times as long as the ordinary transmission lining. That, in a few words, is the story of what Cork Insert Transmission Linings do for a Ford—

They Give the Ford Owner a Better Driving, Better Braking Car and Save Him Money

Ordinary transmission linings become hard and polished from service. Then they slip when the brake, low or reverse, is applied—they grab and slip—causing the noisy chattering, the rattle and the jerking which Cork Inserts eliminate.

The corks in Cork Insert Linings never get hard or slippery. They retain their ability to grip, throughout the long life of the lining. That's why they put velvety smooth, positive transmission action in the Ford and make it a better, safer, more economical car to drive.

Nearly all jobbers stock **Cork Inserts.** If yours can't supply at once, fill out the coupon below and we will see that you are supplied at once.

FAN BELT FOR FORDS

They keep the fan fanning —keep the motor cool —they don't slip

Most motor trouble is caused by overheating. Overheating would largely be avoided if the fan were kept fanning, by a belt that didn't slip. The slippage of the ordinary fan belt runs as high as 25% to 50%.

Cork Insert Fan Belts make the fan turn with the engine, because the slip is reduced to the minimum. The corks are not affected by water or oil, grease or dirt. They retain their gripping qualities throughout the exceedingly long life of the belt. They outwear several ordinary fan belts. Nothing else to equal it ever has been produced. Order direct if your jobber hasn't **Cork Insert Fan Belts,** mentioning his name, and we will see that you are supplied.

A Year Ago—

A Trade Mark and an Idea

BEARINGS SERVICE COMPANY

HYATT

NEW DEPARTURE

TIMKEN

A year ago the Bearing Service Company was represented by a trademark. Today it is represented by twenty-two branches.

The idea itself was one of "service"—a specialized service to automobile dealers, garagemen and motorists.

At each of our branches are maintained complete stocks of the leading types of anti-friction bearings—Timken, Hyatt and New Departure—bearings of every size and description.

In addition to these stocks, there is maintained at each of these branches a detailed system of records—supplied by the bearing manufacturers—which enable us to tell the exact size of bearing needed for any location in any make of motor vehicle.

All we need to know is the make, year and model of the car, and the location for which the bearing is required.

You get the bearing you want at the time you want it—without the delay incident to sending to the factory—and with the assurance that it will fit the location for which it is required.

And remember—when you deal with us, you are practically dealing with the bearing manufacturers themselves. We are the exclusive national representative of the Timken Roller Bearing Company, the Hyatt Roller Bearing Company and the New Departure Manufacturing Company—chosen to render you service in everything that pertains to these leading types of anti-friction bearings.

THAT'S SUPREME AND

FULL LENGTH

FOR years manufacturers have been striving to overcome center spring breakage. The hole for bolts had to go. It was a weak spot. Numerous methods have been devised—but at best they simply shifted the breaking point to another place. Take, for example, the hump construction. It *does* eliminate *exact center* breakage. But at the same time causes as great breakage *outside* of the malleable which holds the leaves together. So in correcting one evil it has invented *another*.

Higgins Quality Springs

FOR REPLACEMENT

really accomplish what others have merely attempted. Through a new form of *nib* center construction center breakage has actually been reduced to an amazing minimum and this without expense of strength at any section of the spring. It has been done, too, without sacrifice of flexibility. There is *no* center bolt—no hole—no metal dug out to lessen resistance. No hump to stiffen resiliency or transfer breakage to other parts. But strength that's *supreme and full length*—a "give" and "come back" which resists and absorbs shocks, promoting utmost riding comfort and guaranteeing spring dependability. Strongest where greatest stress is brought to bear—and sufficiently sturdy at *every* point to withstand hardest service.

A special high grade leaf lubricant is inserted between each leaf before spring is assembled for shipping—preventing squeaks and giving free, easy play that lengthens tire life. No extra clips required—use those taken from old springs. Our confidence—our *certainty* that Higgins Quality Springs will make good in the *extreme* is shown in the fact that

The Same Guarantee Covers Every Point

The most liberal guarantee—simply because there is less likelihood of breakage. You want spring safety—you want riding ease with it. Be sure to get *both* by demanding Higgins.

Ask Your Dealer

He can supply Higgins Quality Springs designed especially for your car. If he refuses write us direct.

Higgins Spring & Axle Co., Dept. 414, Racine, Wis.

Dealers: ***Investigate our proposition. It is a hundred-per-center as a trade developer—because it affords motorists means of obtaining spring service and satisfaction they've always wanted. Write for Discounts and Big Catalog C-1917, listing 500 different designs.***

Educational Data and Free.

To aid motorists in cutting down tire costs, The Goodyear Tire & Rubber Company, Akron, Ohio, announces the publication of an entirely new and complete set of tire service bulletins, in which are set forth the various ways of obtaining more satisfactory tire service.

A noticeable departure from a custom which has too largely prevailed in literature advancing tire information, of enumerating an array of "don'ts" for the tire user, is the positive viewpoint employed. The new Goodyear bulletins, instead of outlining the usual "don'ts," tell the motorist just what to "do" to get real tire service. Valuable hints telling how to add hundreds and even thousands of miles to the life of tires are the keynotes throughout the series.

Naturally the more common tire ills are treated—individually and specifically—with full descriptions of just why and how they occur. More emphasis, however, is laid upon the remedy, and what is more practical—the means of prevention.

The new series of bulletins reflects a knowledge of tires and tire conditions gained only through years of experience in the tire business. Obviously, the information imparted cannot help rendering assistance of great value to motorists.

As a convenience to automobile owners, who wished to obtain big mileage from their tires, all Goodyear service stations have been supplied with these bulletins for free distribution. They will also be mailed free of charge from the main office at Akron, Ohio, upon request.

The bulletins come in a series of eleven and bear the following captions: "How to Increase Tire Mileage," "Proper Inflation Pays," "What to Do for Tread Cuts," "Fabric Breaks," "How to Avoid Scraped Treads," "Premature Tread Wear," "How to Use Chains," "How to Make Inner Tubes Last Longer," "Rim Cutting," "Chafed Side-Walls," and "The Way to Maximum Mileage."

Motor Spirit from Mahua.

The Mysore Economic Journal for June contained the following on the production of motor spirit from the mahua:

Great progress has been made in Hyderabad (Deccan) in making motor spirit from the mahua. The tree abounds in the State, and the authorities gather about 25,000 tons of its flowers every year. Some 10,000 tons are used for liquor, leaving a balance of 15,000 tons, which are at present on the market. Mr. G. E. C. Wakefield, the director general of revenue, says: "We have run several kinds of motor cars successfully for some time on a spirit prepared from mahua at half the cost of gasoline. The annual consumption of gasoline in Hyderabad and Secunderabad is about 100,000 gallons, and we require only about 1,500 tons of mahua to make that quantity." Mr. Wakefield adds: "A cheap motor spirit means a great reduction in the working charges of railways, water pumps, motor cars—in fact every description of power engine."

In order to make the average New Yorker feel more at home, the higher priced cars are equipped with commodious two-inch aisles, iron seats, a stupid conductor, 627 straps and no place to put your elbows.

No More Spring Fixing

when you ride on

Tuthill Titanic Lubricated Springs

Guaranteed forever against center breakage—guaranteed at all points and in every respect for one year

WHEN a spring breaks it must be fixed or replaced. And in seven out of ten cases it breaks at the center. Why? Because it has been weakened by a center bolt hole or center nib.

Tuthill Titanic Springs have no center bolts or center nibs. Instead they are strongest at the center. A patented arch makes them practically break-proof.

Tuthill Titanics can be easily adapted to practically any type of axle construction without extra expense. A special Tuthill Titanic Front Spring for Fords is now made by us. It carries the same broad guarantee of other Tuthill Titanics.

Our proposition to dealers is very attractive. Send for it. Also our 1917 Price List—the most complete price list of spring replacements ever published—and name of nearest distributor.

Tuthill Spring Company

No weakening center bolt

No center nib

OFFICIAL AUTO WIRING GUIDE

The Most Valuable Publication Ever Offered to the Automobile World

It contains 463 guaranteed auto electrical diagrams. Over 100 of these are not available from any other source.

Every diagram is in detail, yet is very clear and is shown as the equipment is assembled on the car—not as the equipment manufacturers show it. It is so clearly arranged and the order is so simple that the newest and youngest men in the auto repair business easily understand it. It is endorsed and used by leading service stations for automobiles, batteries, electrical equipment; in garages and by automobile agencies.

Auto trade papers say it is the best thing ever given to the auto repair men. It took two long years to prepare the guaranteed drawings and diagrams, together with the expenditure of thousands of dollars. Neither time nor expense was spared. Over one hundred diagrams were taken directly from the cars, as no other means was available to obtain them. Many "orphan" car diagrams are shown that were also measured up from the cars. No garage or auto mechanic should be without it. One garage says: "It pays for itself three times daily." It saves the owner's time, allows a garage to turn out more work, makes more and bigger profits.

Increases Efficiency of Every Man

The best electrical auto mechanics become better. Young men and men new in the auto business become fast and accurate. Every man in your shop "speeds up." This Guide gives absolute and positive knowledge you cannot find any place else. Think of it—463 complete comprehensive guaranteed diagrams that any man can easily understand. Every one indexed and easily found.

This Book Comprises 500 Pages, and the Price, Prepaid, is $7.50

Any person sending money and not being satisfied with it, can return the book and have his money refunded.

The Hiatt Manifold.

The Hiatt Manifold Company, of Indianapolis, Ind., are placing on the market a manifold bearing their name, for which they expect to guarantee more mileage to the gallon of gasoline than can be obtained from any device offered heretofore. The manifold and its position on Ford car are shown by the illustrations. It is being sold for Fords only.

It consists of a manifold fitted to take the place of the regular manifold of a Ford, differing from the Ford manifold in that it has a hollow pipe on the in-

The Hiatt Manifold.

side of the body. This hollow pipe takes through it air from the outside, which combines with a water vapor coming from the radiator through the small copper pipe. This mixture passing through the pipe is superheated, due to the exhaust gases passing around the internal pipe, and upon collecting in the dome, this superheated vapor-laden air becomes a gas which, when passed to the intake manifold and becoming mixed with the gas from the carburetor is ready to ignite on the smallest spark.

Tests have been carried on for over a year—averaging from 26.7 miles to 32 miles on Ford touring car, carrying four people. In comparison with tests made on the same car without manifold the average was 17.1 miles per gallon of gasoline. Tests made in zero weather have produced 25 miles per gallon with the Hiatt Manifold. Probably the most interesting tests are those made with Fords of the Smith Form-A-Truck type, loaded with 1500 lbs. of dead weight, and carrying two passengers. One of these tests showed that the Hiatt Manifold increased the mileage 95 per cent. Many of these tests will be reproduced in printed form.

There are many excellent points of advantage resulting from the use of the Hiatt Manifold,—it makes a smoother-running engine; puts more "pep" into the motor—the principle of using superheated vapor-laden air gas results in the reduction and almost elimination of carbon.

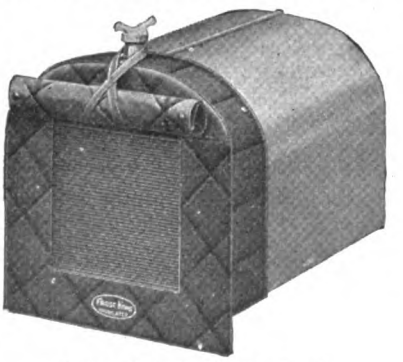
The Hiatt Manifold is sold complete with all minor attachments needed for quickly fitting to a Ford engine, complete directions, etc. It is manufactured by the Hiatt Manifold Company, of Indianapolis. Dealers and those desiring further information, please address the Company at P. O. Box No. 971, Indianapolis. Price $15.00 complete.

Detroit Starter Co. Products.

Every Ford owner has felt that all that separated him from the high-priced car class, so far as the pleasure of driving is concerned, lay in the fact that he did not have independent lighting. Lighting from the Magneto gave him too much light on some occasions and at others no light at all. To install a practical electric lighting system has generally cost him more than he cared to pay.

But now comes the introduction, by the Detroit Starter Co., Detroit, Mich., manufacturers of the famous Versal Products, for Ford cars, of a complete generator and battery electric lighting system, efficient in every respect, at the remarkable low price of $38.85. Ford owners are able to equip their cars with the system and form in every respect to that used on cars costing as much as $5,000.

This system, known as Genolite (six volt) Type H, consists of a Generator, Storage Battery, all wires and installing equipment to light the head lamps and tail lamp with the control switch on the steering post; everything complete, no extras needed. All units are designed according to accepted automobile practice, and contain the latest features of lighting systems as employed on the highest priced cars.



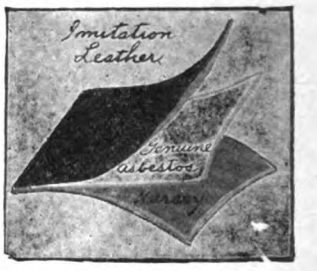
The same company also manufactures what they call a "Speederator," a device which it is claimed gives the Ford car the same flexibility in motor operation as is found in the high-priced six and eight-cylinder cars, and yet its simplicity and low price make it distinctly within reach of all. The price complete, ready for installation, is only $2.85 f. o. b. Detroit.

A Free Counter Card for Dealers.

An easel display card showing Easy-on Chains has just been brought out by the Woodworth Manufacturing Corporation of Niagara Falls, New York, which they are sending to dealers. These cards are printed in colors and illustrate a wheel fitted with Easyon Chains. Easyon Chains attach to the spoke and can be put on in a moment even after one gets stuck in the mud. They appeal strongly to a large class of automobile users who wish for something not too bulky to carry in the car to prevent danger of getting stuck on the road. Dealers handling Easyon Chains can get these cards free by writing to the factory or asking for them from their jobbers.

The Frost King Radiator Cover.

This is the time of year when car owners should think about specialties for winter motoring and a very important



Frost King Radiator Cover.

accessory for the cold weather is a good radiator cover, as this will save gasoline and protect your engine and radiator from freezing. The Frost King Asbestos Insulated Radiator Cover, which is illustrated herewith, is made of the best insulating material known, genuine asbestos, re-enforced with heavy Kersey and waterproof imitation leather. This radiator cover is manufactured by the Cincinnati Auto Specialty Company, Dept. R-107, Cincinnati, Ohio, to whom all inquiries should be addressed.

An Important Contract.

The Pierce Governor Company, Anderson, Ind., has been informed by R. A. Rothermel, manager of their London office, that the Minerva Motors Company, Ltd., of Amsterdam, has formally adopted Pierce Governors as standard

Material From Which Frost King Radiator Cover Is Made.

equipment on their motor trucks and lorries. This is the most important foreign contract closed by the Pierce Govnor Company, as the Minerva Motors Company, Ltd., is among the largest and best known motor manufacturers in Europe. They will require approximately 5,000 governors during the ensuing twelve months.

High-Tension Windings and Condensers.

A fully guaranteed line of high-tension windings and condensers for the trade is manufactured by the Magneto Winding Company, 1723 8th Avenue, Brooklyn, N. Y. This concern makes a specialty of rewinding armatures and coils for all makes of magnetos. Special attention is paid to orders from dealers and magneto repair men, and those who are interested should write direct to the Brooklyn office of this company at the above address.

Vesta Twelve-Eighty a New House Organ.

We have received from the Vesta Accumulator Company of Chicago, Ill., a new house organ called Vesta Twelve-Eighty. This magazine will be distributed only to the large number of service stations which is maintained throughout the country by the Vesta Accumulator Company, for the sale and recharge of Vesta storage batteries, Vesta magneto generators and Vesta automobile electric head lights. The contents of the house organ consists of educational material for the assistance of the service stations in charging Vesta batteries and in general connection with the technical details of the Vesta products.

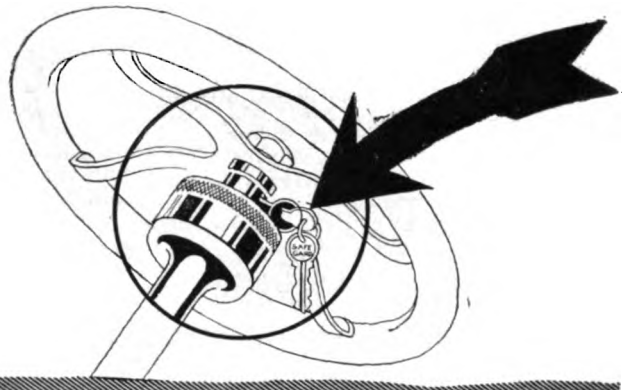
Death of Edward H. Hill.

It is with great regret that we note the death of Edward H. Hill, secretary and treasurer of the McQuay-Norris Manufacturing Company, St. Louis, Missouri, well known manufacturers of piston rings. Mr. Hill died August 11 after an illness of several weeks. He was widely known among the jobbers of automobile accessories.

Digitized by Google

Service by Bearings Service Company.

An interesting use to which the word service has been put is in the name of the Bearings Service Company, Detroit, an organization formed during the past year for the purpose of extending to the automobile dealer and motorist a specialized service for bearings.



"Some people have the idea that we operate a garage and do repair work on bearings," says Mr. Hebner, general manager. "The function of our service, however, is quite different. We do no work on cars whatever, nor do we renew or regrind bearings. We act as a source of supply where garagemen, automobile dealers and motorists may secure any type or size of bearing which they may need in making bearing replacements in motor cars, motor trucks or other motor vehicles. The bearings we sell are a strictly new product, shipped to us direct from the factories where they are made, and we sell them under a factory guarantee.

"This service is of a more technical nature than at first glance appears, due to the fact that there are no two makes of motor cars in which the bearings are exactly alike. This necessitates our having on hand complete data covering the bearing specifications in motor cars of every make and model, as well as keeping in stock at each of our twenty-two branches thousands of different kinds and sizes of bearings so that we can supply every possible demand without a moment's delay. When a garageman or motorist wants a bearing, all he has to tell us is the name, year and model of the car for which it is required, and the bearing location. Our detailed records then enable us to furnish the proper bearing for the installation with absolute accuracy. These records are being added to daily.

"We maintain branches at the present time in twenty-two of the principal cities of the country. At each of these branches we carry in stock complete assortments of the three leading types of automobile bearings, Timken, Hyatt and New Departure. Our stocks include not only bearings of the type used in automobiles of present day manufacture, but of antiquated models and orphan cars as well. Our company being the sole service representative of the manufacturers mentioned above, is naturally working in close co-operation with these manufacturers all of the time. In dealing with us, therefore, the dealer, garageman or motorist is practically dealing with the manufacturers themselves."

Safegard Lock Secures Car.

A lock said to defy the efforts of the most expert thief in that it cannot be smashed with a hammer or broken with a heavy wrench, has been brought out by the Reliance Co., 428, 430 West 38th Street, Chicago, Ill. The Safegard lock is applied to the mechanism of the Ford steering wheel and when the device is locked the wheel is free but has no control over the car. The car cannot be driven or towed away. The Safegard lock has been indorsed by the Underwriters' Laboratories, and each lock bears their label of inspection. The use of suitable and practical locking devices is recommended by the insurance companies, who allow a reduction on theft policies when the machines are properly safeguarded. The Safegard lock is constructed of bronze and steel, and each part is thoroughly tested before assembly. The retail price is $5.00. The manufacturer has a liberal proposition for dealers, details of which will be supplied upon request.

YOUR CAR IS SAFE

IF EQUIPPED WITH A

SAFEGARD LOCK

The best $5.00 investment any Ford owner ever made.

When locked with a Safegard, the steering wheel is free and has no control over the car. Nor can the car be driven or towed away.

Safegard Locks are radically different from any lock made although they resemble some in appearance.

No Hammer Can Smash It

All Safegard Locks are constructed of fine tempered steel and bronze. Each part thoroughly tested before assembling and each lock mechanically perfect before it is placed in your hands. No hammer can smash a Safegard, neither can a wrench loosen it. Safegards are built to endure—and to protect your car.

Reduced Insurance

Safegard Locks have been passed by the Underwriters Laboratories and each lock bears their label of inspection.

Insurance Companies recommend Safegards and allow a reduction on theft policies for cars equipped with them.

You are doubly protected when buying a Safegard—we guarantee the mechanism of Safegards to be right in every degree—and further, a refund certificate is furnished to every purchaser to insure him against loss. Safegards **must** make good.

See Our Exhibit

at the National Exposition for Ford Accessories in Chicago Coliseum, Sept. 22nd to 29th—Booth 193—also exhibit of steering wheel locks for other cars, and the Reliance One-Piece Steel Cable Towline.

Lite-a-Ford.

The Lite-a-Ford is one of the most simply constructed yet efficient light controllers so far designed for use on the Ford Car.

It is so constructed that at low speed the current is intensified, insuring a brilliant driving light whenever such may be required on bad roads.

It is also a most efficient dimmer, absolutely controlling the volume of light at any speed to meet any traffic regulations.

Lite-a-Ford for Controlling Ford Headlights.

Its range of action is great, there being seven distinct degrees of brilliance, ranging from an intense white light to a mere glow, using an infinitesimal amount of current—whenever you wish to leave the car standing and operate the lights on the batteries.

A big feature of the device is its compact form and its simplicity of operation. The entire device is contained in a cylinder 1⅝ inches in diameter and 3 inches long, which is clamped to the steering post at any point below the steering wheel which may be convenient to the driver.

The control is by means of a knurled knob at the top of the cylinder of a size convenient for grasping between the thumb and fingers of either hand and the Lite-a-Ford may be attached on either side of the steering post for the convenience of right or left-handed drivers.

A simple turning of the knob gives any of the seven degrees of light provided by the Lite-a-Ford.

As the question of meeting traffic regulations is of utmost importance with plenty of light when such is needed the Hastings Company submitted their device to the authorities of a number of States where such regulations are in force and not only has the device been invariably approved, but in many cases the authorities have applied them to their own machines and in many instances have officially approved the Lite-a-Ford.

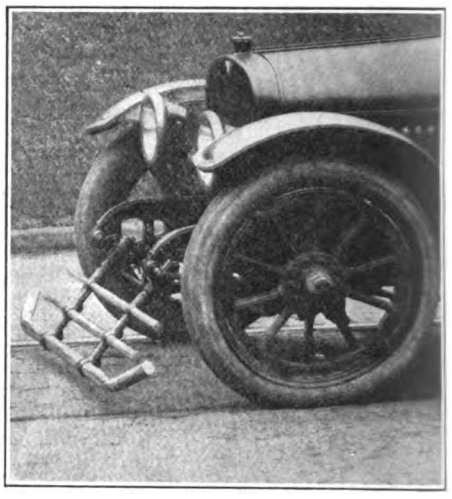
The device sells at two-fifty and is distributed to the trade through the regular channels.

Kimball Tires.

The Kimball Tire and Rubber Company, Dept. 18, 1473 Michigan Avenue, Chicago, Ill., is offering a tire agency proposition, which ought to interest a great many of our readers. The best territories on this tire are being snapped up rapidly because the Kimball tires are exceedingly popular. The line includes the Kimball Bar-Grip tire, the Kimball Button-Grip tire and the Kimball Cord Type tires. This is a line of non-skids, which will sell rapidly. Send your inquiries and orders direct to the main office of the company at Chicago.

Motor Parts Company Deal with Westinghouse.

The Motor Parts Company, 818 N. Broad Street, Philadelphia, Pa., has recently concluded a contract with the Westinghouse Electric and Manufacturing Company of Pittsburgh, Pa., by which the Motor Parts Company acquires the sole selling rights of the Westinghouse Ford starting and lighting equipment. The Motor Parts Company are redistributing the country, appointing agents and distributors, and are well under way with a heavy campaign.



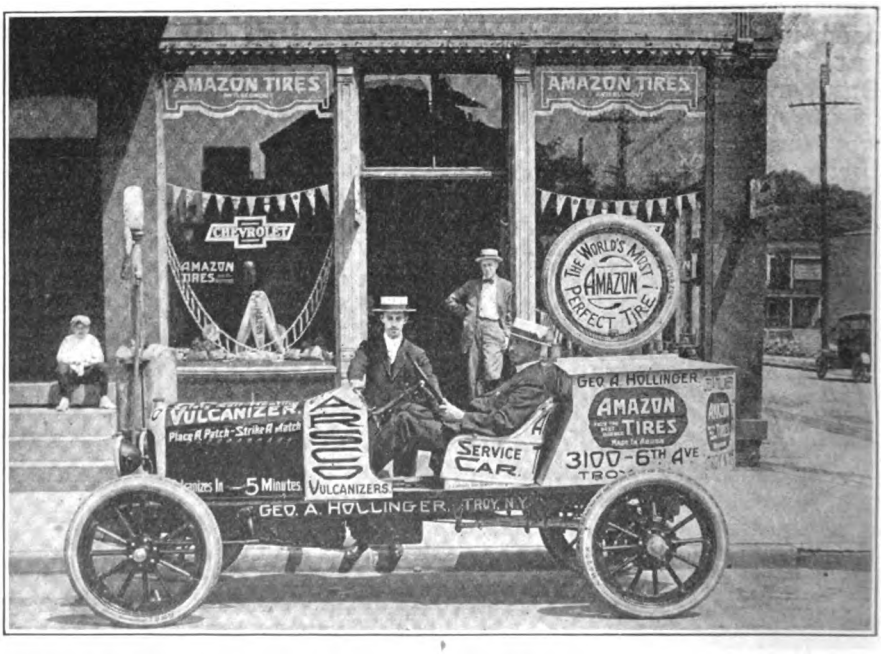
The Simplex Tire Company.

Paul Stanton, who was formerly with Bergen & Zaager, has branched out for himself and is now one of the proprietors of the Simplex Tire Company, 30 West 55th Street. This company handles all standard makes of automobile tires and tubes.

The Sav-a-Life Fender.

The International Sav-a-Life Fender Co., 539 Guardian Building, Cleveland, Ohio, have brought out an appliance which promises to prevent many of the automobile accidents caused by people, especially children, being struck and run over by heavy machines, resulting in permanent injuries or loss of life. The Sav-a-Life Fender, as the appliance is known, is similar to the ordinary bumper in appearance and is adjustable to the height of any chassis.

When the car brings this fender against a person or any flexible object, it automatically releases the fender so it drops within three inches of the road, absolutely preventing objects, especially people, from being run over by any part of the car. While it is constructed to leave nothing to chance, it can also be operated by the driver speedily and easily from his seat. It also takes the place of the ordinary bumper in protecting the car. Should the car hit a stationary object, then the force drives the supporting rods past the release catches, so that it stays in the carrying position as an ordinary bumper. The International Sav-a-Life Fender Company is now operating on a heavy production basis. Thousands of orders are booked. This shows that this fender is meeting the needs and approval of the motoring public. In fact, many sections have approved it by passing laws favoring its use.



The Sav-A-Life Fender.

Novel Advertising Car.

A unique advertising and service car designed by The Amazon Rubber Company for their Troy, N. Y., dealer is shown here.

The car is painted a bright yellow with black hood and running gear.

This Advertising Car Tells Its Own Story.

An inflated tire on a rim is bolted upright on the box.

Besides being a practical service car, it is noticed by everyone on the streets and has great local advertising value.

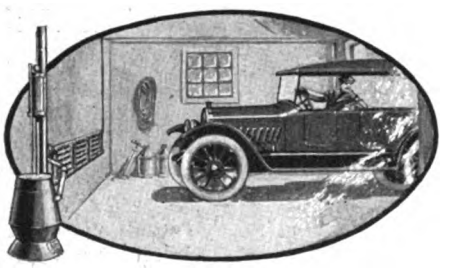
A New Cylinder-Grinding Machine.

To meet the requirements of garages, repair shops, automobile manufacturers, etc., which are called upon to handle grinding of automobile, aeroplane and motorboat cylinders, the Hy-Grade Machine Company, 5606 Curtis Avenue, Cleveland, O., is now building cylinder-grinding machines. The upright frame and lower surface table are cast integral, and the vertical ways and bottom surface are carefully machined and scraped perfectly square to insure accurate alignment. The cylinder to be ground is mounted on a plate which may be adjusted to bring the different bores into the grinding position, this plate being carried on ways that extend the full length of the machine. The spindle is carried in a movable head and may be eccentrically adjusted to travel around the bore of the cylinder, while rotating on its own axis. This spindle is driven by a belt extending back through the ways, upon which the head is traversed, by a screw that is driven in forward and reverse directions by bevel gears. Up and down feed is controlled by a rod with adjustable stops that govern the clutch between the two bevel gears. Revolution of the spindle is controlled by a clutch on a splined shaft driven by spur gears. The fine eccentric feed is operated by a worm or screw furnished with a graduated dial. All operating levers are located at the front of the machine, where they are convenient for the operator. Counterweights relieve the machine of all strain and tendency toward excessive wear. All sizes of automobile, aeroplane and motorboat cylinders may be ground, and it is claimed that the machine is capable of attaining a high rate of production and

Hy-Grade Cylinder Grinding Machine.

doing accurate work. The spindle head is equipped with adjustable bronze bearings, and the spindle is carried by double-row ball bearings and adjustable bronze bearings which are furnished with leak-proof oil retainers. The principal dimensions of the machine are as follows: Height, 6 feet; total travel of spindle head, 22 inches; length of grinding spindle, 16 inches; size of movable plate that supports the work, 16 by 22 inches by 2½ inches thick; working space under machine, 18 by 22 inches, and floor space occupied, 28 by 32 inches.

The cut gives a fair idea of the appearance of the grinder. Readers who are interested should write direct to the manufacturers for prices and more complete particulars.



Election of Officers.

At a special meeting of the board of directors of the Adams-Williams Mfg. Corp., New York City, Francis C. Schwab was elected president. C. D. Williams was re-elected vice-president, and L. W. Schwab was chosen secretary and treasurer. The company is manufacturing and marketing a line of convertible tops or glass enclosures for several makes of well known automobiles.

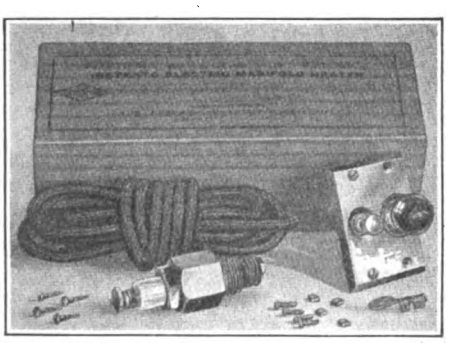
The Wasco Garage Heating System.

Another product that is being brought to the accessory dealer's attention is the Wasco Garage Heating System. This is a coal-burning, self-regulating hot water system, designed to heat private garages holding from one to ten cars. It is manufactured by the W. A. Schleit Mfg. Co., Inc., Syracuse, N. Y. This should be a fine line for the accessory sales-



Wasco Garage Heating System.

man to feature in a dull season. And its simplicity is a great feature. It is shipped ready to be set up, and any handy man can install the equipment in a few hours' time.

So in this constantly growing and developing field there are great chances for a profit building in the accessory line. In the case of the Wasco Heating System, for example, the distributor's profits range from $19.50 to $61.25, according to the size, on each sale. And in the almost innumerable other lines there are equally alluring profits.

The Lepper Electric Manifold Heater.

This is a small electric furnace that is inserted in the intake pipe just above the carburetor. As soon as the "juice" is turned on, it heats up the inside of the intake thoroughly, some of the hot air going directly into the cylinders. As soon as you crank the motor it pulls the gasoline and hot air into the cylinders at the same time, and as a result the motor starts as nearly under summer conditions as modern science can make it. It saves gasoline, batteries, time, patience, cussing and temper. No tea kettle or hot water needed—use hot

Lepper Electric Manifold Heater.

air instead. Let your car stand as long as you like. When you are ready your motor will be ready in a jiffy. Easily installed, any auto mechanic can do it in one hour. Nothing to disfigure your car; the switch is neat, high class and an ornament to any car. Nothing to wear out and will last as long as your car will and then some. It is scientifically correct in principle, safe and is giving 100 per cent. satisfaction to those using it. This is a great seller for dealers. Write for price and full particulars direct to the manufacturers, The Lepper Manufacturing Co., 101 North Federal Avenue, Mason City, Iowa.

Light in the Right Place.

In nearly every state now, there are laws regulating the use of automobile head lights, and some device is required to control the glare which has caused a great many accidents. One of the most practical inventions on the market for this purpose, is the Lennon Light Protection, which is sold by J. H. Faw, Inc., 43 Warren Street, New York City. This light protector, it is claimed, will take the light out of the air and put it on the road where it belongs. Readers who are interested should write to Mr. Faw for full particulars.

Attractive Dixon Display Rack.

The above shows the new counter display rack the Joseph Dixon Crucible Company is sending out to dealers to help them sell more Dixon's Graphite Automobile Lubricants.

The rack is of metal and enamelled in red and black. On the back, for use by the dealer's salesmen, is a chart

Dixon Display Rack for Dealers.

showing the uses of the various lubricants. On the front are spaces for displaying booklets and glass jars containing samples of the lubricants.

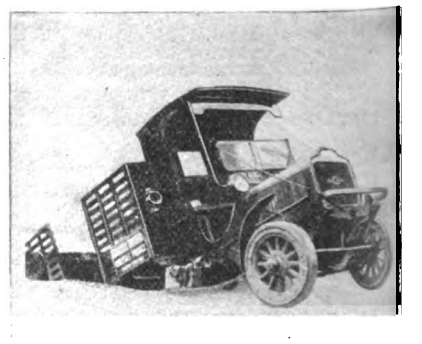
Dealers interested in obtaining one of these racks should write to the Joseph Dixon Crucible Company, Jersey City, N. J., Dept. H.

Rowe Calk Co. Acquires Diamond Chain.

The Rowe Calk Company of Plantsville, Conn., has acquired by purchase the Diamond Chain Company of York, Pa., and the new officers of the Diamond Chain Company are: President and factory manager, Samuel M. Horn, York, Pa.; vice-president, William H. McLaughlin, Hartford, Conn.; secretary, treasurer and general manager, Warren D. Chase, Hartford, Conn.; assistant secretary, S. Ralph Horn; assistant treasurer, E. S. Bestor, Hartford, Conn.

The Rowe Calk Company manufactures the widely and well-known Prest-O-Grip Anti-Skid Chains for trucks with solid tires. Prest-O-Grips, after three years of experimenting and of merchandising in a small way, were perfected and given to the motor truck market a year ago. After a while the Rowe Calk Company found it necessary to greatly increase the Prest-O-Grip manufacturing facilities, and the business has now expanded to a point where it has become necessary for the Rowe Calk Company to have some certain supply of chain to protect the dealer and consumer.

The Diamond Chain plant manufac



Prest-O-Grip Anti-Skid Chain.

tures a high-quality fire welded chain and at present has a capacity of over one million feet of chain. It is to be enlarged immediately to take care of the growing demand for Prest-O-Grips. The chain company will continue to sell its product in the general market.

Drop of Big Truck Does Not Phase Titanic Springs.

En route to Chicago with a load of over three tons of potatoes, the truck in the picture struck a piece of pavement which had been completely undermined by a defective sewer. Without warning, the heavy truck broke through the pavement and dropped with a crash to a point several feet below the level of the street.

Not only did the springs stand this terrific test without a break, but have given thousands of miles of service since

Bad Accident, But Titanic Springs Did Not Break.

the accident, proof that they were not harmed in the slightest.

Tuthill Titanic Springs, made by Tuthill Spring Co., Chicago, Ill., are unique in that they have no center bolt or center nib but instead a patented arch at the center which is held in a vise-like grip by a yoke and plate fastened to the outside of the spring.

A Novel Tire Tool.

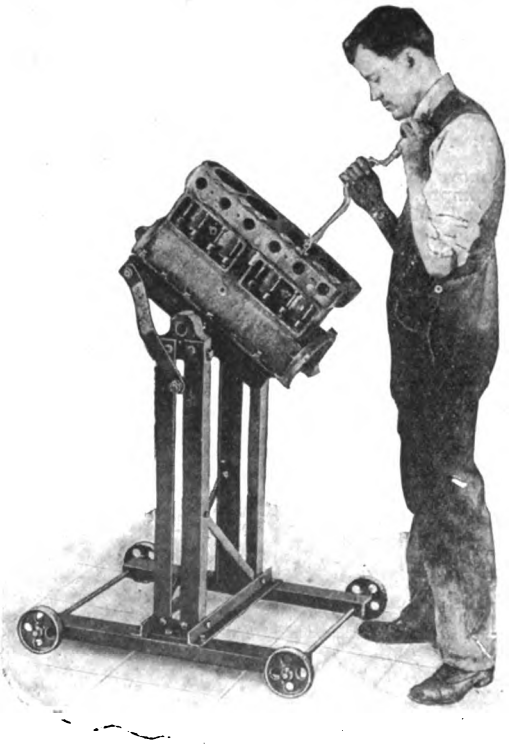
A certain tire dealer, whose name is purposely withheld, has patented and devised a tool that should be of great interest to men engaged in the tire repair business. It fills a long felt want,

A New Tire Tool.

and a description of this tool will undoubtedly interest a great many of our readers. The purpose of this tool is to hold the tread flap out of the way of the operator while making repairs in the internal carcass of the tire.

Repairs on pneumatic carcasses (necessitated by blow-outs) are accomplished in substantially the following manner: An incision is made through the tire extending from near the bead to the opposite side of the carcass and through the tread of the tire to the first layer of canvas. Then lateral incisions are made through the first layer of canvas parallel to the beads of the tread to form a flap. This flap ranges from six inches to a foot in length, according to the size of the injury to be repaired. The canvas carcass is thus exposed and the repair is made in the usual manner. In the meantime the flap, because of its tough and resilient nature, and its tendency to return to its normal position, is a serious handicap to the operator, interfering constantly with the work of repairing. Many expedients have been resorted to to overcome this difficulty, but so far all devices for this purpose have been unsuccessful up to this time. We believe that the tire repair tool here described will perform its function very successfully.

Tokheim Oil and Gasoline Outfits.



We wish to call the special attention of our readers to the meritorious line of gasoline and oil outfits for garages and dealers which is manufactured by the Tokheim Manufacturing Company, 830 N. 1st Street, W., Cedar Rapids, Iowa. This line includes the Tokheim curb post gasoline outfit. This is a self-measuring outfit, which is adapted to use on the sidewalk near the curb, and it enables the motorist to obtain a new supply of gasoline for his car quickly and conveniently. This apparatus is electric lighted at night, making it a continuous advertisement and reminder of service, to attract trade. The Tokheim Oil Wagon, made by the same manufacturer, will save time both for the dealer and his cutomers. This wagon handles both light and heavy oils, so that it may be moved out from the garage to the side of the car. This oil wagon contains two tanks of 20 gallons capacity each, and it is an excellent money getter for any garage owner. Readers who are interested should write direct to the manufacturers for prices and full particulars.

The Lite-a-Ford.

In the August issue of this magazine, we illustrated the products of the Hastings Manufacturing Company, 209 Michigan Avenue, Hastings, Michigan, but in this issue an interesting announcement will be found from this company in regard to their Lite-a-Ford. This is a device for controlling the glare of headlights on the Ford car. By means of this invention a brilliant illuminating radiance is furnished on low engine speed for country driving when most needed, and a variable dimmer for city streets to avoid arrest for non-compliance with city ordinances. The Lite-a-Ford retails for only $2.50 and thousands of Ford owners are already using this very useful specialty.

Engine Stand for Ford Motors.

We illustrate herewith the Every-Way Engine stand, especially made for handling Ford motors in repair shops. This device will save much time and labor on Ford repairs. The stand is so constructed that it can be turned to any position and securely locked in that position, thus placing the engine at exactly the angle best suited to the particular work you want to do. This engine stand is quick, simple, safe and sure in its operation. The stand can be furnished in stationary type, or mounted on four wheels so as to be easily moved around. Repair men who are interested should write for full description and prices to the manufacturers, The United Engine & Mfg. Company, Hanover, Pa.

Every-Way Engine Stand for Ford Motors.

Good Opportunity for Dealers.

A good tire is an excellent selling proposition for any dealer, and in this issue of our magazine, the International Rubber Company, 98 West Tennessee Street, Denver, Colorado, makes a proposition which should interest every dealer in the country. Within the next thirty days, this tire manufacturer will appoint about twenty men or firms in both Eastern and Western territory as exclusive factory dealers in the sale and distribution of Gates Half-Sole tires. The sale of these tires is to be promoted by a very exclusive advertising campaign, including the use of local daily newspapers, and every man who secures an exclusive dealership for these tires is to be given the benefit of all inquiries and sales resulting from this advertising in his territory. Gates Half-Sole tires are guaranteed to run 3,500 miles without puncture and this guarantee is backed by a concern having a million-dollar capital. This is a live opportunity for the right man, and we advise any of our readers to communicate at once either by special delivery mail or wire with the main office of the International Rubber Company, 98 West Tennessee Street, Denver, Colorado.

The Wizard Spark.

This is a new spark plug appliance which has been recently placed on the market by the Modern Tool & Stamping Company, 313 South Clinton Street, Chicago, Ill. The manufacturers claim that this device will put an end to spark plug trouble by increasing the voltage and decreasing the amperage, thus insuring a big fat spark under any condition. The device retails for only $1.00, and readers who are interested should write for terms and particulars direct to the manufacturers.

Digitized by Google

"What Happened to Brown's Car."

The man who knows what it is to be relieved of his car when he left it standing in the street "just for a moment" will particularly appreciate that little tragedy, "What Happened to Brown's Car," issued in folder form by the Walker Ke-Les Lock Company of Chicago, manufacturers of the Walker Ke-Les Lock. The man, who so far has escaped the game of the auto-thief will get a tip or two from the story as to how to insure his good fortune.

In four brief scenes the car owner witnesses how a band of auto thieves work in stealing and disposing of cars. Mr. James H. Cumming, sales manager of the Walker Ke-Les Lock Company, who has made quite a study of the auto thief problem states that the little sketch is more typical and true to life than the average car owner would suspect.

"There has been such a demand for the little story," says Mr. Cumming, "that we are issuing a more elaborate work on the subject of the auto thief in his various species and modi operandi. The title of the new book will be "The Port of Missing Cars." This more general title will enable us to take up more fully the various reasons back of car stealing and the various ways by which the cars all come to "The Port of Missing Cars."

In the present booklet the story, "What Happened to Brown's Car," occupies two pages of a total of six. The remaining four pages are devoted to description of the Walker Ke-Les Auto Lock. These pages explain how the Walker Ke-Les works on a simplified combination principle. No key of any kind is used. To lock his car the motorist simply gives the operating handle (mounted just below the combination knob) a half turn to the "OFF" position and ignition is instantly disconnected and the gasoline cut off. To unlock the car, the driver simply turns the combination knob to the three number combination he has set and all the ignition is connected and the gasoline valve opened. The lock is capable of more than 87,000 changes in the combination. It can be installed on all cars, gasoline, electric and steam. An important feature of the lock is that it conforms with police and fire department requirements regarding cars standing in the streets.

L. Markle Goes to Republic Truck Co.

Lafayette Markle, a man well known in the automobile trade, has resigned the active management of his office as president of L. Markle Company, Chicago, Studebaker dealers, to become vice-president and assistant general manager of the Republic Motor Truck Company, Inc., at Alma, Michigan. Mr. Markle has been in the automobile business since 1890. His career includes five years in New York with the Central Automobile Company, handling imported cars. In 1905, he became mechanical engineer of the Corbin Motor Vehicle Company, a subsidiary of the American Hardware Company. After that he entered the selling field of the Olds Motor Works in the Mississippi Valley. He opened the Oldsmobile branch in Chicago in 1908, and was Chicago branch manager for the Buick Motor Company, in 1910 and 1911. In the latter part of 1911 he became Chicago branch manager of the Studebaker Corporation, and two years later he organized and financed the L. Markle Company, taking over the Chicago Studebaker business. In all these interests it is admitted that Mr. Markle developed a genius as an organizer, which has figured prominently in the success which has made the name of L. Markle Company familiar to the motoring world. The business of that organization is now over two million dollars a year. It was for his organizing quality that Mr. Markle was selected by President Frank W. Ruggles of the Republic Motor Truck Company. This truck concern has made marvelous progress and is turning out trucks at the rate of 2,000 per month. The gross business of the Republic Motor Truck Company, Inc., is expected to amount to more than two million dollars during the coming year.

Mason Tire Enlarging Plant.

The Mason Tire and Rubber Company of Kent, Ohio, is greatly enlarging the present commodity plant on account of increased demand for its product. The improvements include a new warehouse of very large dimensions, also a new cement house, boiler house and mill room. A large restaurant for the employees is now completed and in full operation. The experimental laboratory has been refitted with a complete and extensive scientific laboratory outfit. The experimental, chemical laboratory contains a small calendar and mill, a testing machine, and a press vulcanizer as well as an open steam vulcanizer. A new office building will immediately be constructed, and in the basement of this building an entire printing plant will be installed to be used in connection with advertising Mason tires.

Mosler Plugs at the Front.

J. W. Fischer, sales manager of A. R. Mosler & Company, the well known manufacturers of spark plugs at Mt. Vernon, N. Y., has just returned from Washington with an order for the Quartermasters' Department, for the American Expeditionary Forces in France, for spark plugs, which takes in all the requirements for plugs to be used in all the trucks, pleasure cars, motorcycles and tractors, which are with the American Army at the front. The business was placed entirely on Mica core plugs, and it is needless to say that the quality and not the price controlled the purchases.

$6

F. O. B. Newburgh $8 and $10 for other than Ford or Metz

SUNDERMAN

Vacuum Carburetor

$6

F. O. B. Newburgh $8 and $10 for other than Ford or Metz

Recent Successful Installations of Sunderman Carburetors

BUICK
Mesa Garage
Pueblo, Colo.

"I would not take the Sunderman Carburetor off for $25.00. In my experience of sixteen years as a mechanic I have never seen anything that equals it. It certainly does all that you claim for it and more too." (June 8, 1917.)

CHALMERS SIX
J. W. Hughes,
Stoneco, Wappinger Falls, N. Y.

"Took quite a long trip yesterday and will say the car ran beautifully with the Sunderman Carburetor. While I do not know exactly what mileage I got, I do know it was more than 50% better than the old carburetor." (July 9, 1917.)

GLIDE 30
G. C. Blackwood, Colfax, Ia.

"Have installed the Sunderman on my Glide 30 and I think it is great. It has developed power that I didn't know the car possessed." (May 23, 1917.)

MAXWELL 1916
Chas. C. Kneeland, Groveland, Mass.

"I installed the Sunderman on my Maxwell Roadster and find it is the best thing in the line of a carburetor that I have ever seen. In fact, I am doing stunts with my car that seem impossible to the average car owner. Gave a demonstration to a friend and on the strength of it I am ordering one for him." (May 20, 1917.)

OVERLAND
D. G. Douglass, Washington Mills, N. Y.

"My Overland never ran better since I had it than since I have installed the Sunderland Carburetor." (July 2, 1917.)

REO
Autoparts Supply Co., Portland, Ore.

"Received the Sunderman Carburetor and same was absolutely satisfactory in every way and made the car run as it never ran before. Our customer has praised us several times regarding it." (July 11, 1917.)

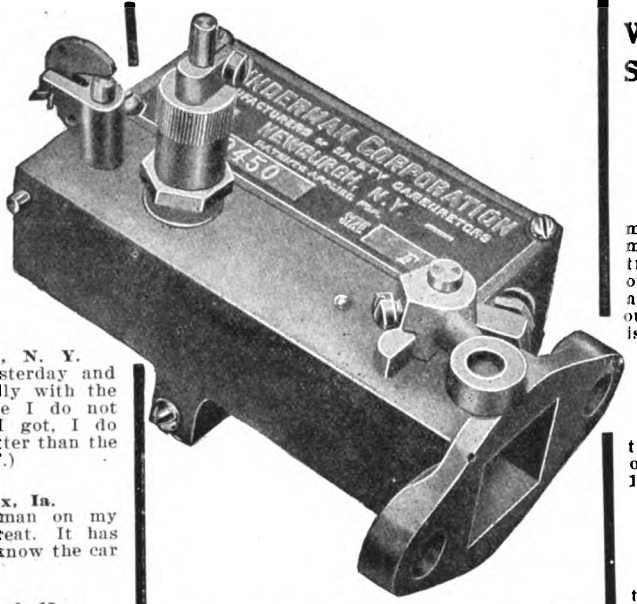
F. E. Howard, Faribault, Minn.

"Have a Sunderman on a Reo Four and it works O. K. Will run on kerosene when the motor is hot." (July 12, 1917.)

STUDEBAKER
Humphrey Auto Co., Lancaster, O.

"Just installed the Sunderman Carburetor on a Studebaker and it is certainly surprising the owner." (June 6, 1917.)

SAXON SIX
Lew T. Wall,
Nev. Consolidated Copper Co.,
McGill, Nev.



"About three weeks ago I installed a Sunderman Carburetor on my Saxon Six and I am much pleased with the performance of same." (July 5, 1917.)

FORD TRUCK
Bourne Bros., Painters, Milton, Mass.

"Have just had the Sunderman Carburetor put on a Ford truck and am much pleased with it." (July 16, 1917.)

FORD TOURING
Thos. F. Jefferies, Makoti, N. Dak.

"Purchased a Sunderman Carburetor for my Ford, and it is so much better than anything I have operated that I would like to obtain the agency for them. Took my machine dealer out for a ride and he said he had never seen a car pick up as that one did. I made a trailer out of my old buggy and took four suit cases, three trunks that weighed 335 pounds and three passengers 47 miles on 2½ gallons of gasoline that tested only 48." (July 19, 1917.)

Read These Proofs of Sunderman Success

In the columns adjoining this we give you, Dealers and Car Owners, absolutely indisputable evidence of the success of the Sunderman Vacuum Carburetor. These letters all bear recent dates.

In the left column we print unsolicited testimonials from owners who have installed Sunderman Carburetors on the most popular cars. We submit them to you without editing them. They speak for us more boldly than we have ever tried to speak for ourselves. Read these indorsements, and then send your order in at once. By all means, READ THEM. Every one has a message for you, whether you own or sell cars.

In the column to the right Dealers from various States, East, West, North and South, speak of their success with the Sunderman Carburetor. When a carburetor makes good so uniformly in localities which vary so widely in altitude and climate, it must be all we claim for it. READ THESE LETTERS, and prove the statements yourself. Send us a trial order, Mr. Dealer, and join the ranks of the Sunderman Boosters.

Help the motoring fraternity to save gasoline. You can DO YOUR BIT by stocking and selling the Sunderman Carburetor, which will save from 30 to 50 per cent of gasoline on any car.

If these dealers find it worth while to sell the Sunderman Carburetor, wouldn't it be good business for you? Write at once for terms.

Sunderman Corporation
13 Chambers Street, Newburgh, N. Y.
Western Office: 403 Kresge Bldg., Detroit

What Dealers Think of the SUNDERMAN VACUUM CARBURETOR

MINNESOTA
Electric Manufacturing Co.,
St. Paul

"The writer is satisfied that the Sunderman Carburetor is a winner, as we have made sufficient demonstrations in the country as well as in the city to convince anyone who cared to observe their workings at all that they are right. We have not, to our knowledge at the present time, a dissatisfied customer." (Aug. 3, 1917.)

MASSACHUSETTS
Herrick's Garage,
Plymouth, Mass.

"I have the towns around me crazy about the Sunderman Carburetor by putting one on cars in the different towns." (May 4, 1917.)

OKLAHOMA
Carroll, Brough, Robinson & Humphrey, Jobbers,
Clinton.

"We are having an exceptionally nice trade on the Sunderman Carburetor, and believe that we will be able to make a cleanup, as they are giving the best of satisfaction. Our salesmen driving cars assist in advertising them extensively." (May 10, 1917.)

MISSOURI
M. & N. Equipment Co.,
1423 Locust St., St. Louis.

"We have a fixed policy that we will not sell or recommend any device until we have tried it for ourselves. In the case of the Sunderman Carburetor we are enthusiastic, and for that reason would like to do something with it." (April 9 1917.)

TEXAS
J. F. Caldwell,
Amarillo.

"Would like agency for several counties. Am using one myself on a Ford and it works fine. Have orders for five." (April 12, 1917.)

NEBRASKA
T. J. E. Pinson,
Platte Center

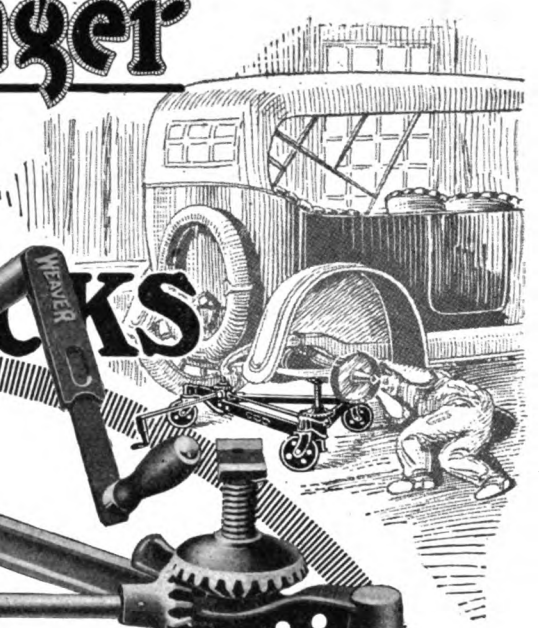
"I now have 43 here working in good shape. They fire the engine all right, pull all right and have plenty of power." (July 20, 1917.)

VIRGINIA
Bittner Motor Car Shop,
Richmond.

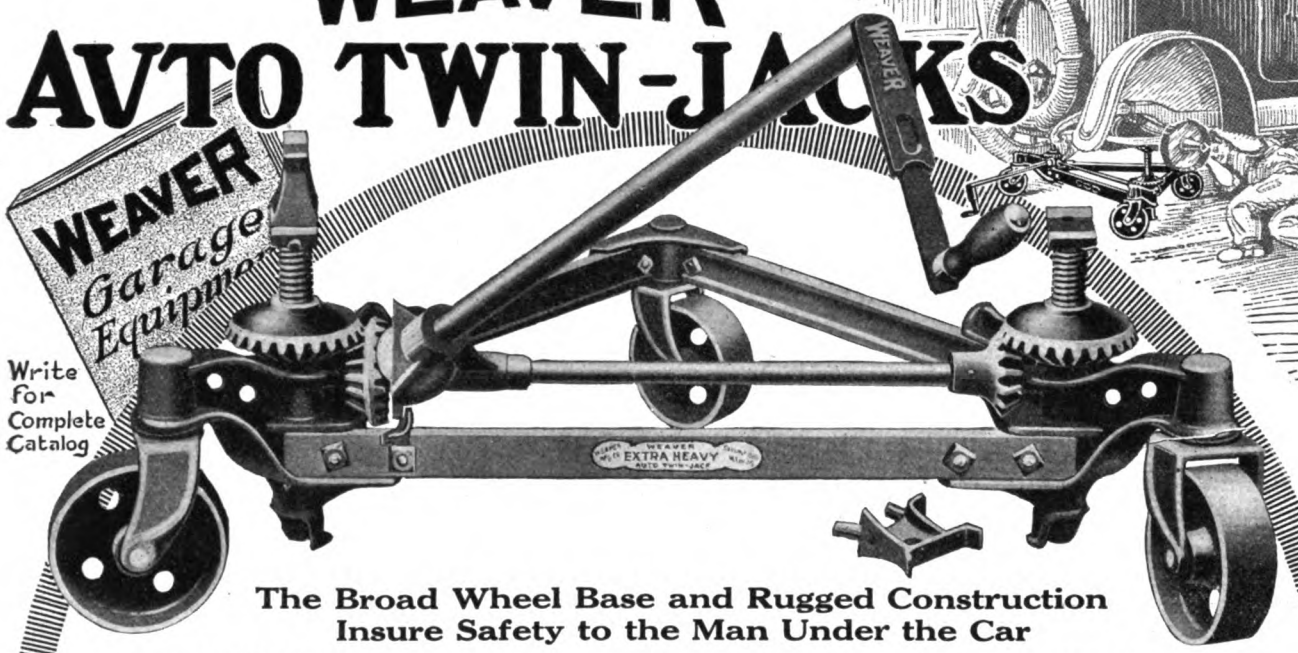
"Have installed Sunderman Carburetors on Peerless 31, Hudson Six and on Fords and cars are doing fine and running excellently." (April 12, 1917.)

NEW YORK
The New Adirondack Garage,
Warrensburg.

"I have used four or five of them and can place at least a hundred more. Ship me two more for Saxon runabouts." May 24, 1917.)



OHIO
Humphrey Auto Co.,
Lancaster



"We have some Sunderman Carburetors installed on cars here and they are working so well the owners could not be persuaded to change under any conditions. What kind of an agency proposition can you submit to us?" (April 30, 1917.)

There's No Danger

in "overhauling" with WEAVER AUTO TWIN-JACKS

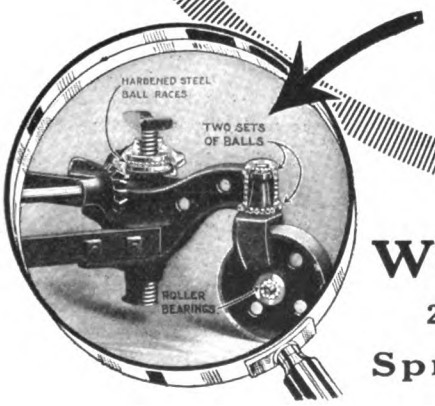
Write for Complete Catalog

The Broad Wheel Base and Rugged Construction Insure Safety to the Man Under the Car

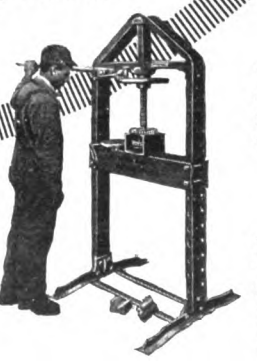
THE feeling of absolute security inspired by the broad, massive construction of the Weaver Auto Twin-Jack enables the machanic to work to the best possible advantage. There is no fear of the dismantled car falling upon him, and he is enabled to move the car at will to facilitate operations.

The dependable crank hoist has no ratchets to be accidentally "tripped" or to jar loose while transporting the load. Every part is properly machined and fitted to insure the maximum of strength and durability.

Always in Service



Every phase of the handling of automobiles demands Weaver Auto Twin-Jacks:—Unloading cars from freight cars—placing them in position on the sample floor—getting out the "buried" car in the garage—placing in closer formation to economize floor space in the storage room—handling dismantled cars in the repair shop—facllitating operations in the wash room and paint shop.



A few turns of the crank handle raises one entire end of the car and supports it firmly and securely upon the large ball and roller bearing casters. With one of these Jacks under each axle, the car can be turned completely around within its own length, pushed sideways, or manipulated upon the floor in any other desired manner. One man can handle the heaviest pleasure cars with ease.

WEAVER Auto Twin-Jacks are scientifically constructed and designed by SPECIALISTS who manufacture nothing but Garage Equipment. * * * Built in two sizes, to meet all requirements.
* * * Will fit either axle of the car.

Ball and Roller Bearings Throughout

High grade ball and roller bearings relieve the friction in the casters and lifting mechanism. Excessively heavy loads can be handled with extreme ease.

Weaver Auto Ambulance

Will handle your "tow in" jobs safely, quickly and economically. Will fit either axle.

Weaver 20-Ton Press

Discard the sledge hammer and do your work in a mechanical manner. This press will soon save its cost, besides increasing your patronage.

Savings made please your patrons and pay good substantial profits.

PREST-O-LITE

Dissolved Acetylene
(Ready-made carbide gas)

adds to the efficiency and usefulness of any good welding equipment. We furnish thoroughly high-grade welding apparatus for $75.00 (Canada $100.00). The average user will also need gas cylinders at an additional cost, and about $10.00 worth of welding supplies. Truck and special equipment for cutting operations at extra cost.

Send for details of Prest-O-Lite Service for Oxy-Acetylene Welding.

THE PREST-O-LITE CO., Inc.

The World's Largest Makers of Dissolved Acetylene

U. S. Main Office & Factory, 820 Speedway, Indianapolis
Canadian General Office, Dept. X, Toronto, Ont.

900 Pages instead of 824 **1918—SIXTH EDITION** 3362 Illustrations instead of 2000

Still $3.00 **Dyke's Auto Encyclopedia** Still $3.00

Entirely re-written, hundreds of illustrations and many new subjects added. Practically a new book. A non-technical treatise with simplified illustrations on Constructions, Operation, Repairs and Adjustments, Cares and Troubles of the Automobile.

There are 50 **Instructions**—Simplified and practical.

3362 **Illustrations**—the kind you understand at a glance.

2 **Supplements**, parts printed in colors, treating on the construction operation, repairing and adjusting of the **FORD** and **PACKARD**—tells how to make a Ford do 60 miles per hour; how to get more mileage per gallon; how to convert into a truck, racer, fine point adjustments, etc.

775 illustrations and 279 pages on **Electric Ignition, Electric Starters** and **Generators**, etc.

51 pages and 254 illustrations on **Adjustments, Tests**, etc., of leading **Electric Systems**.

154 pages and 1189 illustrations on **Repairing**. Oxy-Acetylene Welding, and subjects as Repairs on all types of Axles, Differentials, Steering Devices thoroughly covered—as well as all parts of the **Engine**.

27 pages and 180 illustrations on **Tires and Tire Repairing**.

44 pages and 119 illustrations on **Carburetion**.

89 pages and 291 illustrations on **Engine and Parts**.

16 pages on **Digest of Troubles**.

6000 lines to the **Index**. This is a feature worth noticing, as it means a ready reference on everything pertaining to motoring. **Index** begins on colored paper, easy to refer to.

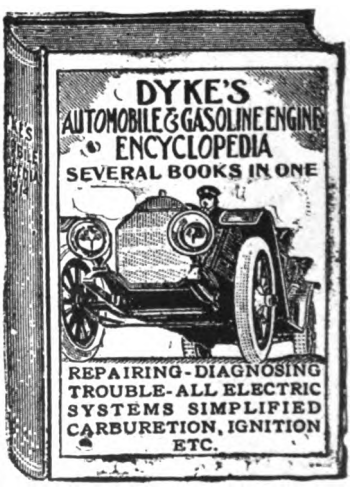
Dictionary is also included, which gives the meaning of motoring terms.

Inserts: There are five—printed in colors. New features you never before saw or heard of in one of the inserts.

You must see this SIXTH Edition in order to appreciate just how complete a book it really is—Order N-O-W.

Price—Although a much larger and better book the price for the present remains $3.00 (or $3.28 prepaid, express).

How to Become an Expert Automobile Mechanician



The quickest and cheapest, but BEST way, is by studying Dyke's Automobile and Gasoline Engine Encyclopedia.

It is a practical, simplified instruction on everything you want to know and OUGHT to know about motoring.

First you learn the principle of construction of each and every part of a car and engine—then the variance of construction—then the adjustments and repairs.

You learn how to diagnose troubles in a scientific manner. Step by step you advance until you are a *real expert* on timing the valves and ignition, repairing and adjusting. You learn the carburetion subject so thoroughly, you can adjust any make.

You will like this book, in fact we will guarantee you would not sell it for three times its cost if you could not get another.

It's worth ten times its cost if only placed on the shelf and used as a reference.

You will also understand Aviation, Truck and Tractor Engines as well as Auto Engines when you complete this book.

Beware of Imitators—this is the *original, simplified* book on REPAIRING, ELECTRICAL SYSTEMS, TROUBLES, Etc. It is the only book in the world combining all these subjects under one cover. Why get three—or four books?

Mr. Dyke published the first practical Automobile Book in America.

Please mail me your book and your dealer proposition.

.....

.....

Driving Nail into Tire Treated with Kor-Ker Puncture Cure. This is the strongest proof anyone can ask and will convince the most skeptical.

Write for Free Test. Try it yourself.

We have distributors in U. S., Canada, England, France, Russia, Norway, Sweden, Holland, Spain, Portugal, India, Egypt, S. Africa, S. America, Australia, New Zealand, Java, Philippines and Trinidad.

We are advertising KOR-KER for you in 25 leading magazines

There's a big, liberal profit in it for you. ***But first make us prove to your own satisfaction that we've got the goods.*** Then let us tell you what other dealers are doing with Kor-Ker.

ALCEMO MFG. COMPANY, 97 Bridge St., Newark, N. J.

JOHNSON
Shock Absorber

Temme

SPRINGS FOR ALL CARS

DO all the lame cars drive to *your* door for Temme Springs and other things?

In most good towns, Temme Springs and Temme's Triple Action Service are known to be *as good as gold.*

Hundreds of repairers, who have "banked" on Temme and never lost, are putting up Temme highway signs today.

These signs *will* bring in business. Temme has tried them, so he *knows.* And now he offers *you* what won for him.

Temme Springs *"for all cars"* means just what it says—for all cars *since 1902.* Test us by naming the spring you need. Temme Triple Action Service will have it on the way to you the same day.

"For all cars" means *designed* for all cars to factory specifications. And so good are Temme Springs—so prompt the service—so fair the prices—that dealers in *all* cars now buy from Temme *in preference* to the car maker.

You need these springs, this service, these signs. They will make you money, bring new business, help you build the good reputation you are after.

If you delay you may lose this exclusive proposition. Write or wire us now, saying: "Send Temme Spring Service Station proposition at once."

This is to remind you of the new model of the famous Johnson Shock Absorber—made by us. The only cure for a hard riding car is a pair of Johnsons. Temme Spring Service Stations make good money on them. Write now for our new proposition.

TRIPLE ACTION SPRING CO., 79 East 28th Street, CHICAGO

Exclusive Top Construction

USL STORAGE BATTERIES

U.S. LIGHT & HEAT CORPORATION

One of the big little things that make USL Batteries last longer is the improved Cover and Filling Tube.

USL Batteries are easy to keep dry, thus protecting the cases from rotting. The hard rubber top of each cell is made in one piece and so constructed as to keep all the liquid inside the battery save when the owner carelessly spills some on top. Even then there is provision to prevent surface short circuits and to minimize the damage.

Lead-antimony bushings are moulded into the rubber top to hold rigidly the posts to which the terminals are welded. This means a solid, non-wiggling joint which cannot leak.

The filling tube enables the owner to add just the required amount of water in a jiffy and without the fuss of measuring the electrolyte level.

These are typical of the details that make USL Starter Batteries with Machine-Pasted Plates the best batteries for a service station to handle.

Write the nearest USL Branch for a list of makes of cars equipped with USL Batteries and why *you* should be a USL Service Station.

U S Light & Heat Corp.

Drawer "G," Niagara Falls, N. Y.

Service Stations in Principal Centers

If there is no USL agency in your town, write us for our proposition.

THE RED ROAD BOOK

250 Pages. Price, $2.00

—and—

THE AUTOMOBILE DEALER AND REPAIRER

$1.00 a Year

BOTH FOR $2.00

A great many of our subscribers will be glad to know that we have made arrangements with the Bullard Co., of Boston, publishers of the "RED ROAD BOOK," on such favorable terms that we can offer this admirably arranged book, size 9¾ x 9¾, and comprising 250 pages, in connection with the Automobile Dealer and Repairer for a year, for $2.00, which is the regular retail price of the book.

In other words, by subscribing to the AUTOMOBILE DEALER AND REPAIRER, the subscription rate of which is $1.00 a year, you get the "RED ROAD BOOK" AT HALF PRICE.

We don't know of any better book than this on the market. It is bound in flexible cloth, and comprises road maps of the following states:

All of the New England States	Pennsylvania	Virginia
New York	Maryland	West Virginia
New Jersey	Delaware	District of Columbia

These states are largely patronized in the Summer by tourists from all over the country, who like to visit the Catskills, the Adirondacks, and the White Mountains. The "RED ROAD BOOK" also gives maps of that portion of Canada reached by routes from Northern New York, Northern New England and Northern Maine.

It further gives 153 city street maps, to which are added road distance tables, ferry tables, and the necessary population and location indices for all towns.

Reading route matter in connection with the principal routes is tersely told, and will be printed in black, and their reverse routes printed in red, to avoid confusion.

The aim in the production of this work is simplicity. Too many automobile route publications attempt so much, that in their efforts to be "complete" they become "confusing." The publishers of this work say that many years of motor travel and the observations of others lead them to the opinion that once out of the confusion of a city's streets, on the broad highway, the need is less for the detailed, must-be-closely followed printed words, comments and instructions of the path itself, but rather the need is for the accurate knowledge that the road to town A and thence to town B is of "automobile goodness," and that it proceeds via this and that village, this or that side of a lake or a mountain, with crossing railroads, or paralleling trolley lines, as a check on location.

Thus is one free to carry out his original purpose; namely, to see the country, with this instruction book.

If with such maps as are shown in this road book, one sees that they are to pass within a few miles of a well-known and picturesque lake, or historic hamlet, or perhaps desire to go "across country," a good road map is the best aid for this free lance mode of travel.

A new edition of this road book is now being prepared, and will be corrected right down to date, and will contain much new material. The book will be ready for delivery from the first to the fifteenth of April.

All orders sent to us will have prompt attention just as soon as the book is issued. In case you have already renewed your subscription, a Red Road Book will be sent on receipt of One Dollar. Address:

Mr. Garage and Repair Man—LISTEN—Dealer and Jobber

IT MAY SOUND TOO GOOD—BUT! NEVERTHELESS IT'S TRUE

Think of it: A "Multiple" valve grinder—grinding Four (4) Valves of a Ford motor at One Time by a single back and forth movement, Saving 50% in time. Satisfying your customer more at less expense and More Profit to yourself.

Yes sirie, it's wonderful—so it has been proclaimed by thousands of satisfied users, who claim it to be the greatest labor saving device on the market.

1. Because it will grind—Two (2) intake and two (2) exhaust valves at one time.
2. A boy can grind in a set of valves more perfectly with our "Multiple" than it is possible for a skilled mechanic by hand with the best of tools.
3. Insures a more perfect seat than hand grinding—account of being bolted down with cap screws and held central and in alignment by a single back and forth movement of handle The valves are rotated 1¼ revolutions and automatically lifted from their seats and reversed 1¼ revolutions, thereby adding greater efficiency to the motor and more satisfaction to the customer.
4. Saves disputes of customers account of too much time spent on job beyond your control—due to the ancient method of hand grinding.

No mechanic necessary to do valve grinding with the "Multiple." A boy can do this in ¼ the time, better and more perfectly, than is possible for a skilled mechanic by present day method.

No drilling or tapping necessary—One minute and grinder is fastened ready for operation. Being held central and in alignment it will insure a better and more perfect seat, adding greater efficiency to the motor and more satisfaction to customer.

Write For Particulars. *Agencies Open.*

FOX TYPEWRITERS

Factory Rebuilt Like New at $65.

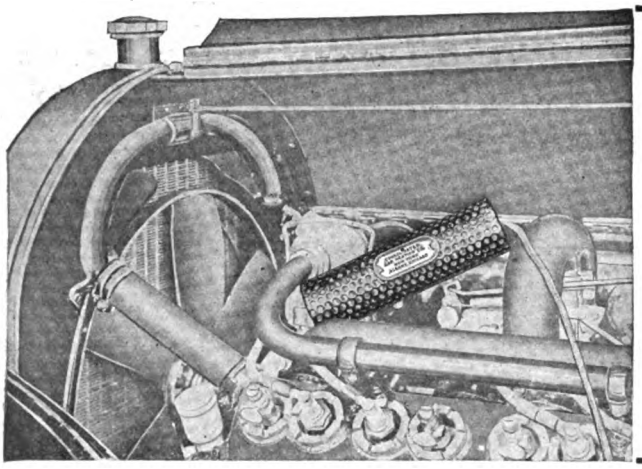
THE LIGHT RUNNING FOX TYPEWRITER

The word "rebuilt" has been abused and misused until it has become a meaningless trade term. When we rebuild a Fox Typewriter we take it all to pieces, re-nickel the nickel parts, re-enamel the frame and replace all worn parts with new ones. The same men who originally built the typewriter do this rebuilding **and do the work just as good.**

50% NEW PARTS AND 3 YEARS GUARANTEE

We offer a rebuilt Fox Typewriter, Model No. 24—*just like new*—for $65.00. These have standard carriages taking paper 10½ inches wide, any kind of keyboard, any kind of type, rubber covers, tabulators, back spacers, two-color ribbons, and are complete with instruction books and cleaning outfits.

Send us any amount you can spare, **from $1.00 up,** as a first payment, and pay the balance $5.00 monthly. Or, send $61.75 all cash. If $10.00 or more is sent with order we will include Free our $4.50 Solid Oak Typewriter Table. Transportation must be paid by the purchaser.



Please order direct from this offer, mentioning Automobile Dealer and Repairer for January. State price you wish to pay and enclose any amount of cash you can spare.

FOX TYPEWRITER CO., 6201-6211 Front Ave., GRAND RAPIDS, MICH.

CONSOLIDATED ENGINE HEATER

Makes starting easy in cold weather. You need this rugged, safe, economical and convenient electric heater to keep your engine and carburetor warm. Attach it to electric light socket in garage and start in a jiffy. Don't heat your whole garage. This safe and efficient little heater applies heat just where you want it, under the hood of the car.

CONSOLIDATED CAR-HEATING COMPANY

NEW YORK Singer Bldg. · ALBANY · CHICAGO Fisher Bldg.

(Largest manufacturers of Electric Heaters for Railway Cars in the World.)

EACH ONE SPECIALLY CAST

The one-piece tight ring with the wonderfully planned joint.

No leakage of gas or oil — more power — less expense.

Don't just try a set — get a set — put them on and feel the "pep" in your motor.

Dealers everywhere.

The Chalsmith Company, 351 West 59th St., Chicago, Ill.

GENUINE

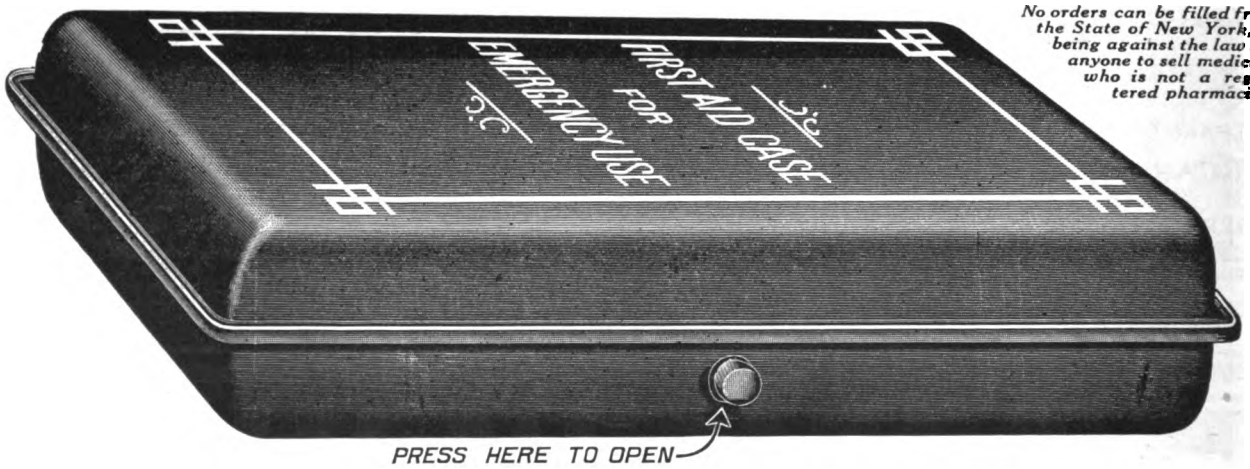
Armstrong Stocks and Dies

FOR THREADING PIPE OR RODS

HINGED PIPE VISES PIPE CUTTERS

Manufactured by

THE ARMSTRONG MFG. CO.,



335 Knowlton St., Bridgeport, Conn.

IT MAY BE YOUR TURN NEXT

TO MEET WITH AN ACCIDENT ON THE ROAD.

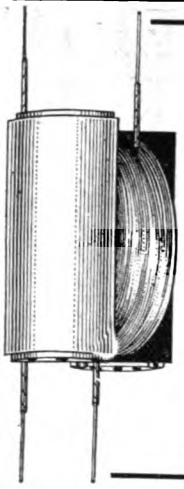
It may also be a case of life and death to have the materials at hand for prompt treatment. We have recently made arrangements for a First Aid Case for emergencies especially for the readers of the AUTOMOBILE DEALER AND REPAIRER.

No orders can be filled from the State of New York, it being against the law for anyone to sell medicine who is not a registered pharmacist.

This case is made of heavy Bessemer Steel, size 11½x5½ and 2¼ inches deep, finished in Black Baked Japan and fitted with a strong instantaneous snap. It is strong enough to resist injury to the contents through accident or dampness.

The contents have been carefully selected to supply the needs in an emergency, before the doctor comes. All gauze, bandages and cotton have been prepared in aseptic laboratories under the same rigid inspection as those supplied to the United States Army and Navy.

The contents of this case consists of:—1 "First Aid to the Injured" Instructions. 1 Yard plain Sterilized Gauze for dressing large wounds. 10 Yards 2-inch Sterilized Gauze Bandages for dressing cuts and bruises. 10 Yards 2½-inch Sterilized Guaze Bandages for dressing cuts and bruises. 1 Package Sterilized Absorbent Cotton for pads and dressings. 1 Box Carbolic Salve for burns, sores, insect bites, etc. 1 Yard 1 inch Zinc Oxide Adhesive Plaster for retaining dressings and covering small wounds. ½ Ounce Tincture of Iodine, an antiseptic for immediate use on all wounds and abrasions. ¼ Ounce Spirits of Ammonia for use in case of shock, heart failure and faintness. ½ Dozen Safety Pins.



The retail price of this outfit is $2.50. We have made an arrangement with the manufacturers of such a liberal character that we can supply this outfit with a subscription to the AUTOMOBILE DEALER AND REPAIRER for a year, for the regular price of the outfit, $2.50.

In case you have already subscribed for this year, we will send you one of these outfits, postage prepaid, on receipt of $1.60, which may be remitted by check, money order, or in any convenient way.

Every subscriber to the AUTOMOBILE DEALER AND REPAIRER should have one of these outfits. It may mean the saving of your own life or the life of some friend. *ORDER AT ONCE AND THEN YOU WON'T FORGET ABOUT IT.*

Profits in H-B Battery Charging

YES, SIR—That's what I'm in business for and this H-B Battery Charger is one of the best money-makers in my garage. $20 to $60 clear profit every month—sometimes more. It's a full 500 Watt equipment, guaranteeing quick charging and quick profits. Recharges one to seven batteries at a time, at cost of 12c to 15c per battery. Autoists pay 75c to $1.50. At least $4.50 profit each capacity run. Uses city current, or belt driven equipment can be supplied for battery charging and lighting.

$15 Puts This Money-Maker In Your Garage

Balance in ten monthly payments of $15 each, which earnings should easily meet and give good profit besides. Send initial payment of $15 with trial order, or tear out this ad. and mail with name for full particulars. You run no risk, as under our guarantee you can return machine if not absolutely satisfactory.

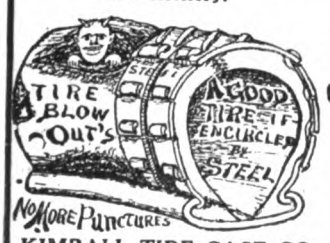
YOUR SPRINGS NEED LUBRICATING!

KNOWLSON'S Spring Spreader

STOPS THE SQUEAK

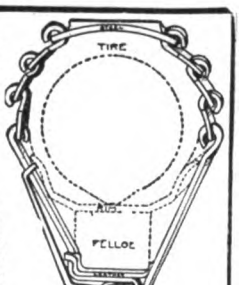
Adjustable to any size spring.

Protected by Basic Patents and Guaranteed.



Money Refunded if Not Satisfactory.

One jolt of a rusty, squeaky spring may cost you ten times the price of this sure preventive.



SPRING LEAF LUBRICATOR CO., 1000 Forest Ave., Ann Arbor, Mich.

Hang on to your old tires. They will last as long as you live if covered with steel. **The Kimball Steel Protector** makes **Blowouts, Punctures** and **Rim Cuts** impossible. A few sections will hold any old blowout. Tires as flexible as ever.

Special inducements to those in new territory.

MUD CHAIN can be put on in a jiffy with one hand while standing on the run board. If you get in a mud hole you will laugh out loud. Hook the ends together and pull the little lever and they are on tight. Good for blowouts.

KIMBALL TIRE CASE CO., 174 Broadway, Council Bluffs, Iowa

We stated in our advertisement earlier this Spring and Summer, "It will be advisable to place your order early, as we are in position now to sell this outfit for $125, but cannot tell how long we can maintain this price, as raw material is going up so fast."

We said it would have to come, but-

that in the meanwhile tire repairmen would be getting the benefit of phenomenally low prices

NOW it has become necessary to advance the price of our

TYPE F

BIG CAPACITY VULCANIZER

SELF-CONTAINED OUTFIT

from $125 to $150. The steadily increasing cost of raw materials has made this absolutely unavoidable, AND NOW WE SAY this is better value equipment by far than is offered elsewhere at anywhere near this price.

Auto Tire Repairing—A Better and Surer Business Than Ever

Regardless of whether people do or do not buy pleasure cars, they will drive the cars they already have—this fact, together with high prices of tires, will greatly increase the demand for tire repairing over what it has ever been before.

WE MAKE A COMPLETE LINE OF TIRE REPAIR EQUIPMENT. Catalogue on Application.

YOUR OPPORTUNITY

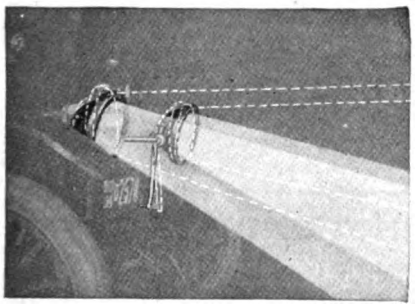
TO INCREASE YOUR PROFITS FROM FORD OWNERS

THE BILL AUTOMATIC SPARK RETARDER

Positively Prevents Pre-ignition and consequent back-firing when starting the motor, thus saving the pain and inconvenience of a broken or badly sprained arm or wrist.

Instantly advances the spark upon the first power stroke of the motor, insuring continued running without the necessity of sprinting back to your spark control.

Is absolutely automatic in its action and requires no attention whatever from the driver.



The long felt want and enormous demand for a device of this kind makes it a rapid seller.

Quick turnover and a generous profit makes it a splendid dealer proposition. Write for details.
